For those of you who are looking at HF mobile antennas, I would like to invite you to take a look at the Carolina Cyclone series of mobile antennas. Slightly larger than the generic units sold on the 'net and at hamfests, these antennas also put out a BIG signal because they do not use PVC anywhere, they use #14 wire (instead of that skinny #16 stuff), and they can be configured with lengths of lower masts to conform to the distance from your mount and the top of the vehicle. That is so that your coil can "peek" over the top of the car. Normally the masts are 3' unless otherwise specified. Additionally, I betcha some of you have bought the "other" brands only to have your weather cover crack and split after a year--or even a few months. I use 1/8" wall Lexan and I have several sizes to fit your particular unit whether it be "skinny" or "fat". Just measure and let me know via my website.

Thanks for reading==and letting me vent about UPS.

73 all,

Jerry
K4KWH

"You got questions and we *make* up answers"

ROTFL !!!!

My Gawds...Harvey.. you are such a Trip !!!

I actually talked to guys in RadioShack.. they are a helpful lot.but seem to have no idea about antennas and such. Just helped me browse through the various CB Antennas. Maybe there were convincing me to get rid of my Shortwave and get a CD Radio ?

> "Ravi R" wrote in a slightly different order:

In a different order eh ? Does that mean i am getting into the barebones of antennas ? lol

Alright.. now. since you have a 7600... i guess we are in the same league..(Albiet you have more points lol)

Actually my house is built of brick and mortar.. and add to that.. metal frames to prevent burgulary...in the windows, making my windows not only burglar proof but also shortwave proof !

And i do get a superb reception, with the whip..extended in the backyard of my house.. but i cant stay out long since it gets cold.

And yes i get better reception when am close to a window.
Yesterday i logged around 50 stations.. from Indonesia to.Peru.. to Chile.
Amazing piece of radio this little guy SONY.
You exactly know what i want.. lol Yes i hate to open up my whip antenna often, and turni it into a Loop antenna.. by mistake.

So a ext antenna is cool.. in the sense that.. i can just place the radio in any position in want in my bed or whatever and listen to stations.

I do agree.. that having a preselector..can get cumbersome.. operating so many switches to get a single station.. and i might as well look like a WWII era Codebreaker.

So i poured though that book and the AN-LP1 actenna had thumbs up from the editors
In their own words..

"Hands down this is the best antenna for portables and a bargain for what it does.."

So i cudnt resist that and i actually found a store in USA that carries that antenna. I admit that the fancy folding option and its performance was a sucker and i gave into it.

But this is just a start.. and after a while i plan to get a tabletop model...and all the circuits and diagrams in the ARRL book are interesting. Actually it has sparked me into designing my own antenna by trial and error and of course some logic.. in free time.

But i will still buy that 10 buck antenna.. and install it.. for i guess nothing can beat.. a passive outdoor antenna..(man .. did i sound..so confident ? its the ARRL book !)

So i wil use the outdoor antenna.. when at home and..the AN-LP1.. when am travelling.

But all your advice is sincerely appreciated Mr.Harvey.

I guess you should actually host a talk show in Radio.."Beginers guide to antennas and cloth hangers" Am serious !!!

And dont feel relieved.. once i get that Wire antenna from Shack.. i might still come up with something to ask you !

:)

Ed,
It should work. Another alternative would be to
have the wire follow the rafter lines instead of the
floor. It would more than double the area of the loop,
which should improve things.
'Doc

Marvin emailed me that he has an MFJ antenna analyzer, so the first method Val proposes is what I'd recommend. You won't, of course, need the transmitter -- just connect the analyzer to the 50 ohm end of the balun with the appropriate resistor at the other end. Since only very low power will be involved, you can use a small carbon film, metal film, or carbon composition resistor -- anything except wire wound.

Of course, this doesn't test the balun's ability to achieve balance, just that its ratio is correct.

Roy Lewallen, W7EL

Rafael:

Tools, no I don't know of any "ready made" or off-the-shelf tools.

But the limitations and the methodologies for broadband matching were laid out by the "masters" many years ago.

See for instance:

H. W. Bode, "Network Analysis and Feedback Amplifier Design", D. Van Nostrand, New York, 1945. (Nice original work on limitations of broadband matching.)

R. M. Fano, "Theoretical Limitations on the Broadband Matching of Arbitrary Impedance", Journal of the Franklin Institute, Vol. 249, No's 1 & 2, pp. 57-83, 139-154, 1950.

D. C. Youla, "A New Theory of Broadband Matching", IEEE Transactions on Circuit Theory, Vol. CT-11, No. 1, pp. 30-49, 1964. (The seminal and definitive modern work on the subject.)

E. S. Kuh and R. A. Rohrer, "Theory of Linear Active Networks", Holden-Day, San Francisco, 1967. Especially Chapters 7, "Broadband Limitations on Network Performance", and Chapter 8, "Theory of Broadband Matching".

The few times in my career when I/we had to do this, we developed the tools ourselves (One time project specific programming efforts in Fortran .) to perform the approximation and synthesis algorithm steps outlined in the above references. Today I would probably do it using MatLab.

As I stated at the top, I really don't know if there are any "general purpose" tools available to solve such problems... the reason being that there are so few such problems to be solved that it simply doesn't pay for a tool vendor to make them available. But that doesn't mean that such tools don't exist, perhaps someone lurking on the NG knows of modern tools for broadband matching... I admit that I just don't know, haven't researched it for years.

Best of luck,

I have used the AEA/Tempo CIA-HF impedance analyzer for several years now
and am very well satisfied with it. I also use the computer program by Dr.
Grant Bingeman for remote control and graphics displays, etc.

I believe that the CIA-HF is currently selling for about $500 - in my view
it is a good investment for a near-professinal grade instrument. Its
ability to present a graphic display over a frequency range of any of
several mesured parameters sets it apart from other, less capable
instruments.

Wes:

I've looked at your site before, nice work BTW...

In the kind of work that you reported it is assumed that the line has a "definable constant characteristic impedance" Zo and loss, which is a secondary parameter, not a primary parameter, is measured (or used) at a single frequency or narrow band of frequencies. i.e. one just chooses a frequency (ham band or whatever) of interest and picks off the loss at that frequency from the graph. In the application the line would only be used/evaluated at that narrow band frequency range where the loss is a "constant".

In the wireline work in DSL investigations I was discussing, the lines are characterized, and indeed used, in a broad band sense. i.e. the characteristic impedance is "all over the map" throughout the signalling band and so simple "one number loss" calculations are not suitable for the computer simulation/evaluation of DSL communications system evaluations. Instead the whole line needs to be simulated across the whole band of interest, including loss and group delay, etc...

I was looking for simple formulas for the primary parameter variations with respect to frequency so that those could be "plugged into" a simulation program.

Thanks for publishing those results on loss of ladder line, neat stuff.

Polarization mismatch loss (dB) between two linearly polarized antennas is
20 Log(cos(T)), where T is the alignment angle. 0 degrees = aligned,
mismatch loss = 0 dB. 45 degree alignment, mismatch loss = 3 dB.

Thanks Doc, great idea...

Is the assumption correct that the alu-strips serve as a kind of
groundplane, blocking some of the interference from the house and
computers,lights and other electrical things in the rooms below the strips?
Maybe also reflecting the signals to receive to the wire?

Thnx again.

I assume that was tongue in cheek, LAN or local apparent noon is the same regardless. A source of real problems to the railroads years ago. The answer was time zones.

In the real world, on HF, either is close enough for "guvment" work. The reality is once your in contact, if your like me, you rock the rotor back and forth to maximize the signal. Getting exact true north is best left to those that enjoy picking fly crap out of pepper. A number in this group eschew the picking...

Best way I have found to extract anything of this nature is to use an old automobile
bumper jack and a chain. You'll have to clamp something to the ground rod, such as a pair of vice grip pliers, to have something for the chain to grab, but

just wind a turn of chain around the rod below the vice grips, hook it up to the bumper jack and jack the rod out of the ground. It will take a few reattachments of the vice grips and chain to finish the job, but it works. You'll have to rig the chain to the jack, as they vary in their construction. This
may be the most timeconsuming part. I chose a jack that had a tab on its head end that fit exactly into a link of the chain I used. I use a bolt and nut to close the chain end below the vice grips.

Works even better at removing steel fence posts.

> the shadow will be pointing to the true north pole...

that works. But it pretty much requires you to sit out there in the
sun for an hour or two watching the shadows move.

A similar, but easier for me, method is to mark the tip of the
shadow at 11am, then draw an arc (use a string tied to the center
point) around the north side of the stake starting at the mark.
When the tip of the shadow touches the east side of the arc, mark
that point. Draw a straight line between the two points on the arc.
Draw a line square from the first line to the stake.

That last line runs true north and south.

Hmm. I've installed several attic antennas in confined attics. Did
you consider taking the antenna up before you unfold it? Usually
that way you can align the boom, then fold out the elements so the
trusses and elements end up interleaved. Then hang it with some
poly rope or use a short mast either up or down. Wire and be done.

> Could/would someone recommend something good? I have a RS set now that is great

I don't think any set top is good. Some are adequate for some
people, but that's the best I can give them.

> at 9 and up but is very weak on 2, 5 and 7. Any help would be appreciated?

That is interesting break. Channel 7 and 9 are much closer in
frequency than are 7 and 5. I wonder if the stations are weaker or
if you have some interference that coincidentally doesn't bother 9+.

Not necessarily...

I wonder what nefarious activity goes on during that fairly long period of time between when you first turn on the PC and when the Zone Alarm software firewall is finally up and running...

One could imagine that a smart and nasty programmer could arrange things such that your PC would upload its secret spyware messages (your personal financial data of course) while Zone Alarm is still waking up, yawning and scratching its little binary armpits. The spyware app might have to access the Ethernet HW directly (perhaps bypassing the OS and its restrictions), but that ain't exactly rocket science.

Let's see, perhaps up to a 10 second window of opportunity at 1.3 Mbits per second... hmmm. Frightening isn't it.

:-)

You should take a look at Ensemble SV available at:

http://www.ansoft.com/about/academics/ensemble_sv/index.cfm

This might do everything you need. I have not used this program at all and it
is a 30M download, so good luck.

I have used Serenade SV, also available at the same site and it might be useful
too. I had trouble downloading it, but an email to the right person got me a
copy on cd. I won't give the address here as I don't want to ruin my welcome.

You should also have you professor(s) look at contacting Ansoft about getting
support and possible free software for your university. There is a link for
that at the same address above.

BTW, I wouldn't call your 3% BW problem "broadband."

Regards,

Wes Stewart N7WS

Hello J Harvey,
You bring up a very valid point and that period of time can be a few moments of vulnerability with some firewalls. I recently switched from Zone Alarm Pro over to Sygate Pro v5 for that very reason you cited. With Sygate Pro 5 this "vulnerable time" is blocked by a component of Sygate Pro 5 that loads before anything else including any network access.

Here is a URL for the new Sygate Pro 5...

Or, 45 degrees is symmetrical between H and V, half & half, thus 3dB down. Blindingly obvious once I thought about it. I didn't really like my first answer ("1.5dB") and that why I suffixed it with a "(?)" - it just didn't seem right.

Thanks.

Well, I can't dialup the internet until the thing boots and Zone is
already loaded so I guess I was thinking in terms of dialup.
>

I suppose so. IF the pranksters and cons thought it was
worthwhile...but thats the argument (one, anyway) Mac users use for
protection :-)

In any case, I think if the majority of online people had some sort of
firewall, the interest and ease of hacking, browser tracing habits and
other nasties would fall by the wayside.

4620. Re: Parametric equations for skin effects in practical transmission lines?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-06 00:21:07 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C8560F3.E6550C4E@eznec.com>
Source record: 147204

One other thing to keep in mind --

In coax, where all the field is immersed in the dielectric, and with good quality dielectric material such as PE or PTFE, the dielectric loss is very low and increases in direct proportion to frequency. Because it increases more rapidly than conductor skin effect loss, it eventually catches up with the latter as frequency increases. Consequently, the dielectric loss begins becoming dominant at somewhere between about 1 and 10 GHz in typical cable.

One would expect, though, that if the impedance were higher, the dielectric loss would be proportionally greater, and the skin effect loss proportionally less. (Higher impedance causing less skin effect loss is the sole reason that open wire line has lower loss than coax at HF.) This would mean that, all else being equal, the dielectric loss would begin showing up at a lower frequency than we see in coax. Also, if the insulation is something like PVC instead of PE or PTFE, the dielectric loss will be much greater, again leading to a lower frequency crossover. On the other hand, some of the field of twinlead line is in air, which will reduce the overall dielectric loss. (The fraction of the total field in the air can be determined by comparing the velocity factor to the inverse square root of the insulation dielectric constant.) So the bottom line of what I'm saying is that before making the assumption that the dielectric loss is negligible, you should take a look at the salient properties of the transmission line to see if it's a valid assumption. Or, if you have measurements over the frequency range of interest, make sure the loss is increasing only as the square root of frequency at the high end of the range. If it's steeper than that, dielectric loss could be significant.

There's something else to think about. Some implanted programs are smart enough to give themselves Zone Alarm permission to send outgoing messages. Zone Alarm pro requires that you enter a password each time you give permission, just to foil this. I don't know if the password feature is included in the free version. If not, it's worth the price to me just to have it. Of course, Zone Alarm or another firewall will go a long way in preventing pernicious software from being implanted in the first place.

The hackers are always at work, so you have to stay up to date to keep ahead of them -- or at least, not too far behind them. But keep in mind that any firewall is a whole lot better than none.

Source record: 147207

Roy:

Thanks for that further input on the dielectric effects.

Actually ANSI T1.417 does reference two additional formulae for C and G of telephone plant twisted pair transmission lines as follows:

C(f) = Ci + Co*f**(-Ce), Where Ci is the "contact" capacitance and Co and Ce are chosen to fit experimentally measured curves.
G(f) = Go*f**Ge, Where Go is the low frequency or DC conductance and Ge is chosen to fit experimentally measured curves.

Clearly the C and G effects are almost negligible in the frequency ranges of DSL systems on plastic insulated twisted pairs, i.e. up to the double digit MHz, since the constants recommended by T1.417 for 26AWG plastic insulated copper pairs have an insignificant effect on the lines performance. The C and G parametric equation parameters recommended by the ANSI document are:

Co = 0.0, Ce = 0.0 with Go = 43nMhos/km and Ge = 0.70.

Over a few years, I have developed several "finite element" transmission line simulation programs (Fortran) for DSL system studies that incorporates a;; four of these parametric formulae for the primary parameters R(f), L(f), C(f) and G(f) of the lines. For arbitrary line lengths, arbitrary load and source impedances, and a variety of other "impairments" such as bridged taps and loading coils, the program calculates all of the secondary parameters of the lines such as loss, group delay, phase delay, return loss, return phase, reflection coefficient, power distribution, etc...

The program is also a useful element in calculating the channel capacity of such communications channels.

But in practice I have found values of the R-L-G-C determining parameters omly for a few different wireline cable types [AWG 26, 24, 22, 19, and Cat 5]. All twisted pair plastic insulated types.

I was hoping to find or develop a wider table of these parameters for other line types to use with the same programs. Program re-use was the objective. But it seems that other transmission line analysis communities do not use the same parametric equations.

Oh well...

4626. Re: What is the "near field?"

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-06 01:01:03 UTC
From: "J. Harvey" <JM001.Harvey@sympatico.ca>
Message-ID: <ITdh8.7262$802.1967820@news20.bellglobal.com>
Source record: 147210

NOTE
Due to the complexity of this posting, I'm going to use 'extra punctuation marks' to (hopefully) 'aid clarity'. The alternatives were 'Excess Capitalization' or 'unwanted confusion'...
NOTE

"VE9SRB" wisely pondered:
> I don't necessarily doubt Chip, I just cannot find any reference
> to the 1/r energy or power dependence in the near-field.
>
> My opinion at this point is that defining a general rate of
> energy decline in the near field is somewhat nebulous because
> the extent and field behavior in the near field is a function of
> frequency, antenna size, antenna type, geometry, etc, etc.

I have found a very nice and highly applicable graph today, but it seems to be available only on a .mil network and I can't access it at home. I'm not going to post the link since you guys (& gals ?) wouldn't be able to access it anyway and a multitude of access attempts might be misinterpreted.

I can describe the graph in general terms. If you're willing to read carefully, I should be able to paint a fairly clear mental picture for you.

The graph title is "Antenna Near-Field On-Axis Power Density (Normalized) For Various Aperture Illuminations" (sort of nails the subject at hand, eh ?) It plots curves of 'power density' against 'near field distance' - *both* axis are normalized back to the 'far field transition point' R(ff) at:

R(ff) = 2 * (D^2) / lambda

(They have chosen this point based on phase error of 1/16 wavelength or 22.5 degrees. 'D' is the dimension of the antenna).

The origin of the graph is placed at position R(ff) and at 0 dB relative 'power density'. The position is plotted on a log scale and ranges from 1.0 = R(ff) all the way in to 0.01, or 1% of R(ff). The 'power density' scale runs from 0dB up to +30dB.

There are four curves plotted:

A: The 1/r^2 'far field' equation is brought along just for reference.
B: Typical horn antenna in the H-plane with cosine amplitude distribution.
C: Typical horn antenna in the E-plane with uniform illumination (or a line source).
D: Typical parabolic dish with the usual -10dB taper.

All four curves start at the origin, R(ff) and 0dB, and the 'power density' increases as we move closer to the source (obviously - so far, not always).

All four curves are fairly indistinguishable until we reach about R=0.2, then they start to diverge.

Curve A continues on its merry way towards infinity. It exits the graph at +30dB and R=0.03. Given its 'arrow like' straight trajectory on a log scale, by the time that it reaches the source (i.e. never !), the 'power density' would probably set fire to the very fabric of spacetime. It is obvious why God/Nature has decided not to follow this particular 1/r^2 path much closer than 0.2 of R(ff). :-) !

Curve B might be the particular case quoted by Gnat in that it follows a fairly straight line (starting at R=0.08) with about half the slope of Curve A . It also heads off towards infinity, but in less of a rush than Curve A. It exits the graph at about +26.5dB and R=0.01. Obviously, it can't be allowed to continue - there is no discussion about where it might be convinced to give up on its deadly quest. Don't forget that the position is a log scale (never reaching the source) and the line shows no sign of averting infinite 'power density'. Frightening !

Curve C is bizarre. At R=0.15 the power density drops by about 2 dB and then it wiggles its way back and forth with an amplitude of several dB heading in an overall direction similar to Curve B, but about 4dB lower. We could give Gnat half credit for this one as well if we're in a generous mood. It is also heading towards infinity, but like a drunk.

Curve D is of particular practical interest since it addresses the original question. Curve D overshoots +14dB to reach a maximum at R=0.1 and +16dB and then it follows what resembles a 'damped waveform' settling on +14dB. It does not show any tendency to increase towards infinity like the other curves. This is very reassuring.

An amusing thought is that if one follows Curve D until one reaches the reflecting surface of the parabolic dish, then one would have to turn around, recalibrate and then follow Curves B or C until one reached the feed horn that illuminates the dish. If it were a Cassegrain, then one might be bouncing around several times. And the infinity problem were rear up again.

Thank Gawd for the 'reactive field' - it takes over from the near field at some point and thereby saves us all from oblivion in a flaming Universes. The graph and webpage makes little mention of the reactive field - but it is discussed on 'adjacent' webpages.

The only curve (of A, B, C, D described above) that approximately follows the Power Density rule of thumb of I=1/r is Curve B ('horn antenna' H-plane with 'cosine amplitude distribution'), and then only starting from about 8% of R(ff) and rapidly heading towards infinity before the graphs runs out at 1% of R(ff).

Although I'll give Gnat partial credit, the best answer about the 'near field' is that 'it is complicated and it depends'. The 1/r rule of thumb is far more of an over-simplification than the far-more-dependable 1/r^2 in the

'far field'.

Given the R(ff) definition of 'near field' used by the author of this webpage, there is far more 1/r^2 in the 'near field' than there is 1/r. All the curves follow 1/r^2 over the **larger** almost-half of a log scale !

Regards,

J. Harvey, Ottawa

Easy...
You need a 2 x 4, pipe wrench and pry bar
put the pipe wrench on the ground rod about and inch from the ground, set the 2 x 4 next to the pipe wrench and use the pry bar to move the rod up a couple of inches. Repeat until rod is out of the ground.

OK, but just one! :)

A Newfie woodsman walks into a hardware store and is looking for a better saw. He complains that his saw must be getting dull because he can only cut a few trees in a day. The salesman says "Sir, I have just the thing for you", and shows him a new chainsaw. He says "This thing will cut more trees in an hour that you can cut all week with your big hand saw!"

The Woodsman thinks "Man, this thing is for me!" and buys it. After a week, he comes back and complains to the salesman "There must be something wrong with the say you sold me! It takes even LONGER to cut a tree than with my old saw!". The salesman is really puzzled, and says "Let me check it out, sir", and starts it up. The Newfie says "HEY!!! WHAT'S THAT NOISE!!!".

Bob.

I tried. I looked at the largest image you stored, at the highest resolution you provided. Regardless, the picture was too small and fuzzy.

Tried opening the picture in PhotoEd, blew it up gently, but the text is not legible at any magnification.

Obviously, the smaller, lower resolution pictures are of no help.

It sounds like a simple design, should be easy to describe in your own words? Not sure, does the picture include the detail of how much distance there is between ground and the bottom wire?

I have a website for the antenna I have developed for AO-40. This is NOT a BBQ grill dish, this is the real thing! Watertight HELICAL feed, NO aperture blockage,2' dish is 20.5 dBi gain, 3' dish is 25 dBi gain. 2" crossboom mount.A true performer. Signals from AO-40 at unbelievable squint angles. You should hear what you have missed! I have also posted tips you may find interesting. AMSAT has expressed intrest in my antenna to be sold at Dayton, but I have a limited supply. Drop by my site and just tell me what you think if you like.

4635. Simple antenna question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-06 09:59:37 UTC
From: Neil <njn2spamspamspamspam@adelphia.net>
Message-ID: <3C85E890.6277ED2@adelphia.net>
Source record: 147121

Dear YL's and OM's,

I want to put up a random length (120 foot) center fed wire, and feed it with 300 or 450 ohm twin lead. I want to run the twin lead through the window and into the shack. Mounted inside the shack is a Palomar 1 KW 4:1 balun, to convert the twin lead to coax.

A short piece of coax to jump from the Palomar to a standard, commercial antenna tuner, using it's standard "coax" position. (I will not be using the internal 4:1 balun of the tuner.) I'll be running 100 watts or less, 10 through 80 Meters, with a 300 watt tuner (preferably not MFJ). I will not confess here that I intend to try it on 160 Meters.

Happy to gather your feedback on the above, although it's a pretty straightforward arrangement, no?

My real question: Is there any advantage to using two wires in parallel for the center-fed wire, "folded dipole style?" Or would that be a waste of copper?

To clarify, I do not mean like "parallel dipoles," but rather like a "folded dipole." Should I KISS (Keep It Simply Simple), and make it a single wire?

Gud DX,
-Neil / wb2cir-

Hi:

There is another circuit analysis program called "NOVA-686".

NOVA-686 is more powerful, and faster than Ecap.

Ecap is shareware. I think Ecap costs $69.00. "NOVA-686" is freeware.

You can download NOVA-686 from:
http://nova2002.com/

The resolution marked "1024" is not the highest resolution picture.
Use the selection marked "Original". I found this one to be perfectly
readable. Everything is crystal clear.

Just use the simple dipole and do not try to make it the folded diople
style. The folded dipole will not work very well over the frequency
range of 80 to 10 meters. If you can make the antenna wire around 130
feet long overall.

Neil,
Why not try both of them? Start with which ever one
would be easiest to put up. Give it a fair chance to see
how it performs. Then try another one.
Especially if you plan to try 160 meters, longer is
better, and so is higher, but you know that...

John,
Thanks for your reply. I've contacted GAP to verify resistance readings I made on the coax and the GAP:
1. coax center conductor IS NOT connected at the GAP as I'd originally thought
2. capacitor connected between center conductor and top of vertical will look different at the coax input (an inductor as you noted)
3. verify where the source is connected in the model

Regards, Jim

I wrote:
"The feedpoint of Arnold B. Bailey`s 1/4-wave folded dipole is 35.6 ohms." Wromg!

Arnold B. Bailey`s 1/4-wave folded dipole has a radiation resistance of 35.6 ohms.

I slipped out of gear at that point. Maximum current is opposite the feedpoint in a 1/4-wave folded dipole, not at the feedpoint. Radiation resistance is determined at an antenna`s maximum current point. So, radiation resistance and feedpoint resistance don`t coincide in this 1/4-wave folded dipole.

Since the 1/4-wave folded dipole has a lot in common with a 1/4-wave short-circuit stub, the impedance at the feedpoint is very high. It is not an open circuit because the antenna has a radiation resistance, even though its ends are shorted. Actual feedpoint resistance is said to exceed 1000 ohms.

50 ohms would be transformed by a Q-section of 300-ohm line to 1800 ohms.

In the MULTEE antenna, 70 feet of twinlead was used as a 1/4-wave at 80-meters.

52 feet of twinlead was used as a feedline between the 50-ohm radio and the high-impedance antenna. That should be going in the right direction.

A 1/2-wave feedline could be used to measure the antenna`s feedpoint impedance. A matching section length could then be calculated. The arrangement found in "The Radio Handbook" probably worked in the circumstances in which it was installed.

I used the wrong feedpoint impedance for the 1/4-wave folded dipole. Mea culpa!

Best regards, Richard Harrison, KB5WZI

"Peter O. Brackett" wrote:

> Question for the NG: ...T1.417...

I'm just catching up on my r.r.a.a reading and was _very_ interested
to find this thread. It's been yet another education in reading through
it, even if somehow the first four notes came in last here and
had me wondering for a while about where and when it started .

I'm the original coordinator of the T1E1.4 spectrum
compatibility/management project and original author/editor
of what became T1.417. My 1995 ramblings survived
word-for-word (to my surprise) as the first, descriptive
half of Annex B. I was the T1E1.4 Secretary until
I retired from Bell Labs last July.

Charles Cook of BT Labs (British Telecom) developed the
formulas that are the subject of Peter's original question.
Before that tables of R, L, G & C versus frequency were
(and still are) used most of the time. (Bell Labs sometimes
used equivalent curve-fitted formulas for internal work.)

If I recall correctly Charles did some _highly_ educated
guessing and trial and error to find formulas that match
closely with cable measurements. These measurements
were/are done with extreme care on _representative_
samples of common cables and at a reference temperature.
Then he runs a curve-fitting routine to calculate the parameters.
He ran the 24 AWG and 26 AWG data on small chunks
of cable supplied by BellSouth.

Cable parameters vary during a production run, though
not as much in these days with laser-drilled diamond dies
as they did with hardened steel dies. Cable parameters
vary from one run to another for a given manufacturer,
and then of course for different manufacturers.
Note that the formulas are for the temperature of measurement,
typically 70degF, and do not account for the -40 to +140F
experienced by real life cables. [Feel free to convert to Celsius. :)]
They do serve as a common reference point for many
different people doing comparative performance calculations
on competing transmission schemes.

Other, older, software code used by Bell Labs
and other telephone labs does compensate for the changes
with temperature, mainly in resistance.

This can result in several dB change in loss at high
frequencies from dark to daylight for a cable
hanging on poles in the desert.

I don't know of anyone but telephone people who have
adopted this particular set of formulas.
ETSI TM6, the European counterpart to North American T1E1.4,
and ITU-T Q4/SG15 have adopted Charles's formulas.
ETSI TM6 has a document with more coverage of the
various metric telephone cables used by various countries.

I believe I have Charles's original paper.
Drop me a note and I will dig it out.
I _think_ John Cioffi, Stanford U., has a set of software code (C?)
developed by his graduate students that is available.

Ken Kerpez, of Telcordia, has implemented the Annex B
DSL performance code at his web site.

http://net3.argreenhouse.com:8080/dsl-test/index.htm

Telephone cable loss vs. frequency is one output of Ken's code.
but not impedance, and only for standard terminations.
I've been meaning to talk to him about adding some more
general options. Use of the site is free, just drop him a note at
kkerpez@telecordia to register for an ID.

Anyone can download one free copy of T1.417
and other T1 telephone standards by searching down
through the menus/buttons at
http://www.t1.org

Work on T1.417 Issue 2 is proceeding with inclusion of VDSL
and mutual interference among remotely located, outside plant
systems being the main additions. I believe the target to submit
the new issue to ballot is the end of the year.

Peter says, "... I have developed several "finite element"
transmission line simulation programs (Fortran)..."
Could I talk you out of a copy of them?
I only have a compiled version of a similar,
but more limited, program and I can't make
any changes - frustrating.

By the way, speaking of VDSL,
VDSL spectra runs 138kHz to 12 MHz.
Originally it was going to be up to 20MHz.
It may be extended down to 25kHz.
RFI ingress/egress has been of interest/concern,
particularly among the hams involved.
I arranged for Ed Hare, W1RFI, to run ham radio interference
tests in the Phoenix area where Qwest has some 50,000
pre-standard VDSL systems deployed. USWest/Qwest

had been very careful in installing these systems
with attention to cable balance, replacing old cable, etc.
Ed had to lay his antenna on top of the VDSL box
to pick up much. I think he has a report in his RFI
area on the ARRL web page.

Cheers, 73,

Ron McConnell

I think ladder line all the way from the antenna to the tuner using
the built in 4:1 balun if needed is more straightforward. I'm not a
great fan of throwing coax between a ladder line feedline and a tuner.
>

Waste of copper, and it will transform the impedance, which may or may
not cause problems.

You might be interested, FYI only...

Since in the DSL application the transmission lines used are very long and operated over a very broadband frequency range, there are no regions over which the primary R-L-C-G paramaeters of the transmission lines can be considered zero or even near zero. i.e. the "lossless line" approximation, the "distortionless" line approximation, etc... simply don't hold for this application of technology, and neither do any of the usual approximation used in narrow band methods, for example the methods of calculating excess loss due to non-unity VSWR etc...

In fact the charateristic impedance Zo of these lines is not constant for the frequencies of interest and varies all over the map with both frequency and of course length which is usually unknown in the telco loop plant. The typical total DC resistance of these lines runs up to 1500 Ohms, resulting in huge losses by ham radio standards and the VSWR takes on a huge range of values. Yet the new advanced modulation DSL technologies are able to communicate over such lines at very high bit rates.

And so the measurement techniques and methodology used by the ANSI T1E1 group in developing the ANSI T1.417 characterization of various twisted pair transmission lines for "broadband" DSL use over the frequency range of zero to 30 MHz might be of interest to this rraa newsgroup. The ANSI and ASTM D 4566 transmission line characterization methodology was as follows:

They used two carefully measured samples of each line of length x meters, where: x = 10 meters length for measurements below 2 MHz, and x = 1 meters length for measurements between 2 and 30 MHz to determine the (frequency dependent) primary parameters of the lines.

Using high quality HP/Agilent Vector Network Analyzers, they measured the complex short circuit impedance Zsc and open circuit impedance Zoc of the

two line samples at each frequency. They tested at many equally spaced frequencies throughout the range zero to 30 MHz. Subsequently these experimentally measured quatntities were used to calculate the characteristic impedance Zo and propagation constant "gamma" at each frequency as follows:

1.) Zo = sqrt(Zoc*Zsc)
2.) gamma = (1/x)*arctanh(sqrt(Zsc/Zoc))

Then at each frequency using relatively very small steps from zero to 30 MHz they calculated the (frequency dependent) primary transmission line parameters R, L, C, G as:

3.) R = Re[gamma*Zo]
4.) L = (1/w) Im[gamma*Zo], w = 2*Pi*f
5.) C = (1/w) Im[gamma/Zo], w = 2*Pi*f
6.) G = Re[gamma/Zo]

Finally to "smooth" the tabulated results and to obtain simple equations for later computer simulations they "fit" the whole range of tabulated results to the following four heuristic "model" equations for the frequency dependent primary parameters R(f), L(f), C(f) and G(f). (I presume that they did a mean square fit, but they don't say how they did it in the T1.417 document.)

7.) R(f) = (Ro**4 + a*f**2)**(1/4)
8.) L(f) = (Lo + Li*(f/fm)**b)/(1 + (f/fm)**b)
9.) C(f) = Ci + Co*f**(-Ce)
10.) G(f) = Go*f**(Ge)

Where: Ro is the DC resistance, and "a" is a constant "fit" to characterize the rise of resistance R(f) with f due to the skin effect. Lo is the "DC" or low frequency inductance obtained at frequencies near zero, Li is the high frequency inductance obtained at frequencies near 30 MHz. "fm" and "b" are parameters chosen to best "fit" the tabulated measured data for L(f). Ci is the "contact" capacitance or DC static capacitance, and "Co" and "Ce" are chosen to "fit" the tabulated measured data for C(f). Go and Ge are chosen to fit the tabulated measured data for G(f).

The ANSI/ASTM groups measured and characterized a lot of different twisted pair cable types and published the results in T1.417.

Repeating just two of the examples that I gave further up the thread:

AWG 26 Plastic Insulated Cable:
Ro = 286.2 Ohms/km, a = 0.14770
Lo = 675.4 uHy/km, Li = 489.0 uHy/km, b = 0.929, fm = 806.3 kHz.
Ci = 49 nFd/km, Co = 0.0, Ce = 0.0
Go = 43 nMho/km, Ge = 0.70

ANSI Category 5, LAN cable ("Cat 5")
Ro = 176.6 Ohms/km, a = 0.0500
Lo = 1090.8 uHy/km, Li = 504.5 uHy/km, b = 0.705, fm = 32.570 kHz.

Ci = 48.55 nFd/km, Co = 0.0, Ce = 0.0
Go = 1.477 nHoh/km, Ge = 0.91

Using such data I had developed some finite element transmission line simulations (Fortran) which are quite flexible and useful for calculating transmission line performance under different complex source and load impedances such as the seconday parameters of: loss, phase delay, group delay, return loss, return phase, etc... using the four equations and their parameters as inputs to the program algorithms.

And so again...my interest is/was to determine if any of this body of work be applied to amateur radio transmission line work? And if any work on amanteur style HF transmission lines used a similar methodology resulting in values for the heuristic model parameters.

It might be possible to extract some of the heuristic model parameters from your ladder line measurements. I'll have a look see.

BTW... the T1.417document should be available from ANSI's New York office, or perhaps from Global Engineering Documents.
I hope this summary of information on the recent ANSI ASTM transmission line testing was of interest to our rraa newsgroup.

Best,

--Peter K1PO

Hi Peter,

Hmm, a fractal transmission line specification. I can see how it
might be useful for my swept frequency amateur radar.

The ARRL 19th edition of the "Antenna Book" says on page 7-2:

"The simplest and most flexible (and also least expensive) all band antennas are those using open-wire, parallel-conductor feeders to the center of the antenna as in Fig 4."

What`s to argue with?

Best regards, Richard Harrison, KB5WZI

Electric fence insulators are designed to be nailed to a post and hold the hi-V wire a couple inches from it. The same insulaters nailed to a roof could let one have a near invisible outdoor dipole. Not the greatest antenna but I gotta believe it'd be better than the same wire *under* the roof inside the attic.

No, of course not. Somebody has to supply the aircraft that are flying across the pond. It might as well be Collins. I just think 8.33 kHz. spacing is the lousiest engineering decision I've ever seen. The error bandwidth for aircraft AM is about +/- 10 kHz and the adjacent channel is then within this error band. Sucks, doesn't it?

You 120 ft dipole is 1/2WL on 3.9 MHz. It is probably not resonant on any
other HF ham frequency. Your 4:1 balun, designed to see 200 ohms will probably
never see 200 ohms. IMO, a 1:1 choke would be a much better choice. Check
out my web page. My All-HF-Band dipole is 130 ft, very close to your 120 ft.
Check out the optimum lengths for feedlines for all the HF bands.

Folded dipoles do NOT make good 10m-80m antennas. Simple dipoles do.

Reg wrote:
"Who said?"

Bailey gives a table of resistances at the terminals of a folded dipole for differing wavelengths end-to-end:

1/4 > 1000 ohms
1/2 = 300 ohms
3/4 = 1000 ohms
one = very low
1 1/4 = high
1 1/2 = low
1 3/4 = high
2 = very low

The relative sizes of the two (or more) conductors is involved as is the spacing between conductors, but these data fit some folded dipole and give an idea of how the resistance varies as the size or frequency of the folded dipole varies.

Best regards, Richard Harrison, KB5WZI

...and put the balun outside the window (waterproofed of course).

That way you have only 1 hole to worry about.

The coax will also be sheilded so you will not have to worry about the spacing between the twin lead and the window frame. Remember that anything that comes in contact with the twin lead will affect its performance.

My solution for this problem was to install a 3 ft. extension with coupler between my Ethernet card and the data line. This extension is routed around my monitor in such a way that the coupler is located below and in front of my monitor. It is a simple task to disconnect the line at the coupler before boot-up, then re-connect it after Zone Alarm is up and running.

Also, I use a little proggie from Computer Associates called Mail Watcher v1.0 (don't know if its still available) to detect anything in an email or news article that is trying to execute. Yes, Zone alarm (Pro) catches most of the nasties, but some can slip by, and are nailed by Mail Watcher.

BTW, most of you would be surprised at how many emails try to "call home" when they are opened - and I'm not talking about opening email attachments. Yes, some emails are SPAM that have managed to slip through my filters, and it's the spammer's way of verifying receipt. I love thwarting the scum bags...

Just my 2¢ worth...

Hi Richard:

The folded dipole is really a loop antenna with the dimension in one direction generally being much greater than the dimension in the other. Being a loop, its impedance at very low frequencies, where the antenna is small wrt the operating wavelength, will be very low - very low resistance and very low +reactance (like most other antennas that operate in a "loop mode").

As the operating frequency increases, the folded dipole will first exhibit a parallel resonance where the reactance will very quickly change from a large +X value to a very large -X value. This occurs at a frequency where the folded dipole has a length *somewhere (?)* near 1/4 wavelength. At this parallel resonance, the feedpoint resistance will be very high - most likely in the order of several thousand ohms. Recognize that in a parallel resonance, the actual resonant frequency and antenna impedance is very sensitive to minor changes in the antenna structure. The antenna will essentially have no usable bandwidth.

I'm not certain what significance there is to Bailey stating that the "radiation resistance" is about 36 ohms. From a practical perspective, it does not have much significance because we are left to match and feed the antenna at its feedpoint. Efficiency can be determined once the loss

resistance referenced to the feedpoint is known. From my perspective, knowing the feedpoint impedance is more important than knowing the radiation resistance at the current max.

Anyway, as the frequency increases, the folded dipole will exhibit a more well behaved series resonance at a frequency where the dipole length is somewhere near 1/2 wavelength. Being a loop, its resonant resistance will be higher than that of the regular dipole. The well know 300 ohms.

From: aa1ll@email.com
Message-ID: <e85be400.0203061324.153499a1@posting.google.com>
Source record: 147160

At http://www.qsl.net/aa1ll there is a nomograph relating number of turns, resonant frequency, and helix diameter, from an equation found in Yusof and Hassan, "Regression Analysis of Resonant Frequency... of Normal Mode Helical Antenna," TENCON 2000 Proceedings, Vol.2, pp228-231.

The equation (converted from metric and rearranged) is:

N=(905/(f*D))^1.25 with

N=number of turns
f=MHz
D=diameter, inches.

It seems to match experience and published designs fairly closely. Note the lack of dependence on helix length and winding pitch for practical dimensions.

I'd like to know if anybody uses it, even to compare with other designs.

> Is the ARRL Antenna Book the authority on the subject ?

The dipole described in Fig 4 costs about $20 and works on all HF bands.
That's pretty simple and flexible and inexpensive. And I *am* an
authority on *cheap* antennas. :-)

Neil-
I do not know the problem.
It looks fine to me.
Click on the thumbnail.
Select 'original'
this will take you to
http://www.edebris.com/catalog2/browse/63/0/0/0
It's a 700 pixel wide JPEG image and looks great.
If you don't want to wait as long for the load use this URL
http://www.edebris.com/catalog2/browse/63/0/0/50/

I've described this before and you may have looked
already.
It's a full wave loop. 80m around. 10m tall sides.
Feed is at center of a side.
Bottom wire is 3m off the ground.
Top wire is 13m off the ground.

It's a copy of an old 10m broadside radiator
from a pre WW2 handbook that is turned on it's side
and scaled for 80/40 use.

Tom:

Heuristic... heh, heh... I love it.

What was it that great Engineer Oliver Heaviside said around the turn of the 19th century or thereabouts when the "Mathematicans" told him that his p-transform was not right, and other "Engineers" said his transmission line theories were a crock of jelly jam, he said, "I know they are right... because they give me the correct answers!"

Heh, heh... Who cares if the method has no basis in Science if it gives the correct answer? Ever wonder how your calculator or computer come up with values for the sine function? Heh, heh... that would make you wonder!

In any case, those heuristic model transmission line equations for the transmission line primary parameters produce answers that "exactly" match measurements of actual systems in the field, over and over again.

I don't know where/who/or what came up with those simple equations, or if they have any basis in Physics, but they seem to work.

Best,

--Peter K1PO

Um, no sir, I'm suggesting that the tolerance is between 3 and 4 kHz, depending on whether you are at the bottom end of the band (3.5 kHz.) or the top end of the band (4.1 kHz.).

If you have a transmitter that is off with a positive max tolerance and a receiver that is off with a negative max tolerance, you have to allow 8 kHz on one side and 8 kHz. on the other side for your receiver error budget. If you then factor in a 3 kHz. audio sideband outside of THAT, you've got to allow 11 kHz. each side of center for the error plus modulation. If you go further and figure in the tolerance for your IF filter, it comes out more like 15 kHz. a side. Now tell me how in the hell I'm supposed to discriminate against something that could be as close as 4 kHz. (including THEIR tolerance) to band center when I've got a 15 khz. wide IF bandwidth each side of center?

Makes you wonder how those airborne UHF AM sets manage to work at 3
times the frequency with only 25 kHz spacing don't it? And, then there
are all the other tight tolerance satellite systems sandwiched in
between.

The Europeans have now figured out that they have to either hire air traffic controllers with six arms, or three times as many of the usual two-armed variety. :-)

More fairly, they had a problem to solve 'Right Now' - they couldn't wait for another decade or more for VDL to be fully implemented. The rest of the world has more time than Europe.

John-

Looks like E X H, "what's a reactive field?", to me.

The short answer.

Poynting's math only describes the physics, it doesn't define it!

The medium sized answer.

How does an antenna work?
Current changes direction in a wire and some of the energy is radiated.
How much is radiated?
It's proportional to the current times the length(vector) over which the
current
travels. This means an amp of RF in a 30' piece of perfectly conducting
wire gives the same radiation as 30 amps 1 foot piece of the wire.
This is all you need to compare antennas.

If the goal is maximum radiated energy, in the desired direction,
for the lowest cost, the entire system should be examined, not
just the antenna.

Work up a budget.
db/dollar for signal processing
db/dollar for antenna
db/dollar for rf generation

Doesn't make me wonder in the least. The airborne UHF sets are military, and if you tell me that I've got to hold 0.001% tolerance, I'll simply tack the crystal heater onto your military bill and send you on your way. We know how to hold a frequency to 0.0001% (150 Hz. or so in the civilian air band) over temperature if we wish, but the cost to a civilian purchaser would be out of sight. Of course, the civilian **is** the purchaser of the military equipment, but since they have no say as to how their taxes are spent...what can I say?

There should be a copy, at in least hard form
in one of my boxes, of Charles Cook's paper.
In those days (1996?) , very few T1E1.4 documents
were submitted in soft form. Now everything is soft.

For lack of a formal title, I have been called the "chief facilator"
for the VDSL Coalition, sometimes "coordinator,"
and sometimes, "cat herder." I answer the email "phone."
Other than our webmasters, there is no formal structure,
even though we have about 70 members
of all sizes from around the world.
On the VDSL Alliance: one can show that equally well
designed and equally well built systems using
either DMT or CAP/QAM linecodes have equal theoretical
performance for data rate, loop range, interference
and loop impairments.
We (naturally) disagree on which is more practical for VDSL. :)

"...ideas for something completely different!" Hmmm...?

I'll send you my phone number.

Cheers,

Ron

How about doing as I do: turn on the computer and let it boot, during which time ZA is loaded and "awakens."

THEN, I go online after ZA is alert and doing its thing. Also before going online, Norton's Anti-Virus has been loaded and is watching every incoming and outgoing file.

Seems to me like there is little or no problem for we poor dial-up access guys, but even with 24/7 access, I see no reason why one's defenses cannot be up and running before actually going online.

Wonder what I am missing here?

In QLD Australia, there is a place called Indooroopily. The locals say it as In-dro-pilly and if you call it in-door-oo-pilly (as it is spelt) all you get is a blank glazed stare, or blatant laughter! And Goondiwindi - said 'Gun'diwindi. Plenty more where these came from, too!

BTW - calling all US citizens - please say Aluminium for me (remember - there is two 'i's in Alumin'i'um) :-) [had to get that one in!]

I remember a thread in sci.physics on this subject of pronunciation and there was some wierd example of how the word fish should be spelt, based on the sounds in fish compared with other words with similar sounds. Can anyone rermember this?

Jase.

Ed,
I doubt if the metal strips block any interference from
your house. Unless they are gronded, and much closer together
than I think they are, they wouldn't act as any kind of
shielding. Neither would they act as a reflecter. if anything,
I would suspect that they would 'detune' the antenna. You won't
know till you try it out, and you probably won't be able to
tell they make any difference at all.

My component audio system has an FM antenna. It is a short length of wire connected to a terminal at the rer of the tuner/amplifier. On a certain station the reception is mediocre. It improves greatly when I simply hold the wire. Is there something I can attach to the wire that will replicate whatever my body is doing to improve reception?

The magic length for the antenna wire is around 2.5 feet for best efficiency. About all you can do indoors is to orient it for best reception and tack it into place somehow, maybe under the shelf. With an outdoor antenna, even a simple one, you can avoid the problem altogether.

Ah, but----In the US it is spelled without the second "i" so their
pronunciation matches the spelling. In Canada, we have a split personality,
eh -tend to use either form for this and many other words. However we do
have our own names such as Tsawassen or Iqaluit and the ever famous
Saskatoon, Saskatchewan. I like Newfoundland place names such as Dildo and
Conception Bay, but other provinces have their own such as Alberta's Moose
Wallow, etc.

If it is a standard ground rod, and there is nothing on the top of it to prevent what I am suggesting, why not use the Hydro method. Most garden hoses I have ever used have a larger inner diameter than a ground rod outer diameter. Just use water! If the garden hose won't fit over, then you can fashion a piece of pipe to the end of the garden hose and "hydro-drill" around whatever it is you need to remove. One of the two ways may work.

Yep, add a longer wire to it, or use a real FM antenna hooked to those
terminals. IE: dipole, etc. Radio shack has fm antennas. A TV antenna
will work fine. Indoor rabbit ears could work. MK

Sorry, couldn't restrain myself.

This blonde has a business that goes broke.
That night she prays to God: "please God, help me, I'm out of business,
out of money. Let me win the lottery."
That night the lottery results show that someone else wins the lottery.
So the blonde prays again to God with the same request, but the next
night, again someone else wins the lottery.
When she sits down to pray for the third time, the sky bursts open with
a loud bang, and a heavy voice drones: "Listen, girl, you gotta help me
a little bit here, buy a lottery ticket !!"

Used to have a Gap Titan (80-10) vertical in the backyard mounted on the tripod mount of an old C-Band TV dish. Worked great until an ice storm snapped it in half about 3 years ago. Very low noise on 40 and 80 meters.

I believe it was George Bernard Shaw who spelled fish "ghoti" - gh as in enough, o as in women, ti as in action.

So much for the rules of English pronunciation! Of course George was not an Englishman.

Reg,

If my generalized posts or statements waste your time, don't read them. If you want concrete or exact numbers then ask a direct question with specifics rather than criticizing the general discussion.

The problem with your concern over an exact number is the following. Let's presume that I model or calculate (based on some derived formula) the resonant resistance of a folded dipole at its first parallel resonance (somewhere near 1/4 wavelength) and the number I get is 4,532 ohms. Does that help you understand the behavior of this antenna more than saying that the resonant resistance is greater than 1000 ohms or that it is several thousand ohms. I can guarantee that when you and 4 other people build the antenna and measure its resonant resistance there will be 5 new numbers that may range from 2,000 ohms to 8,000 ohms depending on a great number of factors the model and formula did not account for. There will also be 6 different numbers for the exact resonant frequency.

I don't see the real problem with generalized statements or range of numbers in a discussion of this type.

> bands due to extranous loading on unused coil turns.

I attributed it to distributed capacitance between
the coil turns, but... whatever. It's not a hugely
serious problem because the rest of the antenna is
beginning to act as an 'antenna' at those higher
frequencies which tends to swamp out the power
absorbed by the unused-coil resonance. And I have
to confess that I don't look for a 50-ohm match
but rather something I can handle with a tuner
back inside the vehicle. Seems to work, though.
I talked to a JA on 17 while waiting to get on
I-10 here in Phoenix.

Reg wrote:
"From where does Bailey obtain his numbers - whoever he is."

Arnold B. Bailey was a consulting engineer who also shared what he knew in lectures and seminars. There have been testimonials in this newsgroup from attendees of his seminars a half century ago. I am sorry I never met him but I prize my copy of his book "TV and Other Receiving Antennas".

Bailey says in part, of the folded dipole:
"We can class the folded dipole from a circuit standpoint as a closed loop having a total electrical length equal to approximately twice its over-all length. From this viewpoint, it is clear that FIRST RESONANCE will occur when the total circuit or conductor length is one half-wavelength, or a nominal over-all length of one quarter-wavelength.

At first resonance we can expect the resistance at the antenna terminals RA to be high and equal to ZA^2/RR. If we can assign proper values to ZA and RR (as we will do shortly), the resistance at the antenna terminals is easily computed. Bailey shows his work for the next 6 pages in producing the values I posted after going back and reading what Bailey had done.

Best regards, Richard Harrison, KB5WZI

Dan et all,

Hey I live here in CA, Yucaipa (Ukipa) to be exact and am a native of the state. I agree about living too close to LA. That is why I came east to Yucaipa back in '76.
I have 1/2 acre against the hills here and have never had a problem about my antennas or tower. Had two towers early on but now just the one. Yucaipa was not a city back then but now it is. We do have a tower section in the building codes but limit for the tower height is 65 ft. I'm up to 93' at the top of my VHF/UHF vertical and mast with X9 and A3WS. All they care about is the tower height. Lots of building going on with smaller lots size, etc and presume there are CC&R's all over the place.

A good radio club in town and my repeaters add to the emergency radio coverage for the local Fire dept and County RACES groups. Public service and good publicity has gone a long way to create a good image for Hams here.

A few don'ts with twinlead are:

A: Never coil it up. This will create all kinds of problems.
B: do not use foam filled twinlead for ham antennas
C: use proper standoffs made for use with twinlead.
D: Never place it next to metal, siding, roofing or whatever, as it will couple capacitively
F: do not use the clear plastic stuff, as sunlight and weather will deteriorate it very fast. It was not made for outdoor use.

I imagine there are more.
You can often use very long runs, this depends in part on the elevation of the antenna.
As for when to use 300 or 450 ohm, this depends on the need/design of what you are using it for.

Have not seen Mr. Bean since I left Rochester NY in 99.
Mildly amusing is he.

As for the antenna bit, he can add more wire, or use a longer one.
Also, changing the location of the wire may help.

4731. References on Half wave end fed top loaded vertical ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-07 19:56:42 UTC
From: KA9CAR <nospam@nospam.usa>
Message-ID: <a68ght$1f8c$1@news1.tribune.com>
Source record: 147019

I am planning to do some antenna work this summer, anticipating that the decline in sunspots will force me down to 30 and 40 within a couple of years. My all band doublet is only around 30 feet in the air so it's radiation angle on 30 and down is high.

I would like to try a Vertical, but elevated radials are out of the question, which eliminates a 1/4 wave Vertical.

This leads me to a half wave, end fed vertical, with a simple ground for the tank circuit.
My trees are only about 35 feet tall, but they spread out as they go up (maples).

I envision a "top hat" of 2 coil loaded radials stretched through the top of the tree, and a vertical wire hanging from that, down to the feed point.

Any body have a book or web site or article they want to recomend, as reading for this project? Getting the top hat into the tree will be difficult enough that I don't want to have to do it twice!

John

Hi John, I believe you're asking specifically about the "Super C" antenna? From previous posts on this, it doesn't appear to be a very effective design. It's basically a resonator that significantly leaks RF (as far as I understand it).

In spite of some of the critical remarks about Gap antennas, my Titan has served me faithfully. It's an excellent all-band antenna, but you can't expect too much of a simple vertical. As for the fellow who didn't follow the suggestion to guy the antenna, I have no sympathy. I really like not having to lay out and maintain radials and with a minimal effort to attach guy ropes, the antenna is totally wind-proof. Like never washing and waxing your car, then complaining that the paint is no good.

No offense, Larry, but Yucaipa... sheesh... you may as well be in Kansas. You're certainly not where 99% of Californians are, which is in the urban or suburban zone.

But I am glad that you are essentially free to do what you like with your antennas. We all should be so fortunate. Have fun out there.

Al

I only saw one picture, that with the graphs, and could not see anything
legible in it.
You have, evidently, a poor design in your web page, and poor resolution in
that one picture that did show up.
So it is not just one person that has problems.
JFTR, I saved the picture and used Vue Print Pro to open it.
I run Win 2K and 800 X 600 screen resolution.
I also do a lot of work with many photos.

4736. Re: Parametric equations for skin effects in practical transmission lines?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-07 20:48:46 UTC
From: Ron McConnell <rcmcc@earthlink.net>
Message-ID: <3C87D230.8A5F9581@earthlink.net>
Source record: 147024

For anyone interested, I did find JOHN Cook's
(not Charles Cook, another friend) papers on cable modeling
in Adobe Acrobat pdf. The main paper is 555kb.
A short typo correction addendum is 62kb.

John describes the measurements, skin effect,
sensitivity to errors for each parameter, curve fitting, etc.

Temperature was not included since the goal
was to have an agreed reference cable model at one
temperature for parties to compare competing systems.
I don't know whether he has since added the well-known
copper resistance vs. temperature relation to his model.
Other telephone cable simulation routines
do include temperature. I may have to drop him a note.

There are 4 more papers by John and others
(about 600kb total) of interest that show measured data
and the derived Cook parameters. The parameters
are in T1.417, but not the measured data
or any discussion.

There is nothing special about the model to
unshielded twisted pairs. It could apply
to nearly any metallic transmission line.
I am not aware of any non-telephone use so far.

Just drop me note off-line if you want copies.

Cheers, 73,

Ron McConnell

I salvaged one by using an automobile bumper jack.
They have a very good lifting ability.
Main thing is to have a good quality one that does not slip, and good support under its base, as well as something that will get a good grip on the rod.
The one I yanked was in sandstone, so was not easy to get started, but once I did, it came out with relative ease.
I've also used this type of jack to pull posts and to break the bead loose on a tire.
Mine has a piece that fits into the slot in some bumpers, but I use a piece of chain that will fit onto that bit.
And always be prepared for something breaking.
Wear safety glasses to protect your eyes.

From: Ron McConnell <rcmcc@earthlink.net>
Message-ID: <3C87D7AA.2BE6D20F@earthlink.net>
Source record: 147027

I forgot to mention that the T1.417 twisted pair telephone
cable models are usually good to 30MHz.
They are used for VDSL system data capacity calculations
for >= 26Mb/s of digital data using up to 12MHz
of analog spectrum through 3000 ft (~ 1000m) of 24 AWG
or about 64dB at 12MHz.
Since xDSL signals start at about 14dBm total spread across
the 12MHz, that gets to be qrp in a hurry.

For xDSL purposes, there is little usable data capacity
and useful outside telephone loop plant range above 12MHz.

Cheers, 73,

Ron McC.

No offense AL, we are almost among the urban/suburban areas you refer too. Maybe you don't know how close those urban/suburban areas are to me now. Our town
went form less than 20K in '76 to almost 45K now and other towns near by are 100K to 200K strong. So we are on the short path to joining all the rest of the
Southern California. The interstate, I-10, corrodore from Redlands all the way to Banning to the east is building out with housing for the masses. I will be
retiring in a few years and may look elsewhere, not Kansas as I prefer shaking ground over a vacuum to the stars, and will leave this area and try to
remember when it was "Way Out There!"

I am sure I'll have a heck of a time finding a place to play with antennas at my leasure as I can now.

BTW, there are quite a few of us here and lots of towers showing on the skyline.

"K7JEB" wrote:
> "Call Albuquerque Center on 1-2-8 point 4-5-8-3-3"

My information regarding the new bandplan is as follows:

... (for example)
Channel "121.000" is actually 121.0000 MHz (wide BW)
Channel "121.005" is actually 121.0000 MHz (narrow BW)
Channel "121.010" is actually 121.0083 MHz (narrow BW)
Channel "121.015" is actually 121.0167 MHz (narrow BW)
Channel "121.020" is skipped !
Channel "121.025" is actually 121.0250 MHz (wide BW)
... (etc.)

I'm not sure if they bother with the tens of hertz or not. Probably
doesn't matter eiher way given the tolerances.

So they don't really have any more digits to worry about than before -
still just six digits. And they never have to explain 'bandwidth' to
the pilots.

:-)

Ron:

Thanks for the pdf files of those papers.

I had hard copies of all of those at one time, but I left them in my offices
at my previous employers when I left a few years ago.
I am still amazed at how closely those simple models can predict actual
impedance and insertion loss on real lines.

I'll share my finite element analysis Fortran programs with you when I get
them "cleaned up" for general use.

Did those Phoenix area Qwest VDSL systems that Ed Hare tested for interference have the amateur band "notches" implemented in the VDSL transmitters? Do you know whose VDSL chip sets were used in those Qwest systems? Were they Savan/Infineon or Broadcom's QAM systems or the DMT systems?

Radio shack sells a scanner type Discone that also does well for 6 meters
and up transmitting.
It sells for $59.95, and should be available at a store in your area.
I'm using one at this time, and it does quite well.
This is a modified Discone, with a loading coil and whip above the top.
I have about a 1.5:1 match on mine all across the 2 meter band.

You can buy a small inexpensive "dipole" antenna at RadioShack and other stores that sell hi-fi gear. Your best solution is a small FM antenna mounted outdoors. If you have a TV antenna mounted on the house, it will work very well on FM -- you will need a special splitter so you can feed the TV and FM at the same time.

Regards

Pete

I guess you guys use your brains, and I use my brawn? I use a pipe wrench to loosen them up by spinning the rod around then pulling it out depending on the soil and the length of the rod, on occasion some persuasion is need in the form of a lever.

Date: 2002-03-08 03:26:30 UTC
From: Kenneth Fattmann <na0y@worldnet.att.net>
Message-ID: <GbWh8.21376$gK2.1591932@bgtnsc04-news.ops.worldnet.att.net>
Source record: 147044

I am looking for a gent named Neil that helped me with a A4 problem last fall or any body else that can help me with a new problem.

Had a 15 meter trap on the driven element flash over and left a carbon trail. Cleaned up the trap and now workes fine but have no substance to re-coat the trap winding. Does anyone know what the product is that Cushcraft paints on there bare aluminum wire they use in these traps. It must be rather good at RF frequencies and a good high voltage insulator.

I have now idea what caused this trap to flas over unless it might have been what looked like a small peice two of what looked like grass. Any ideas?

Thanks es 73 de Ken NAna0y@worldnet.att.net or na0y@arrl.net

I've never heard them use more than 5 digits so far in the real world.
Many times just 4. But so far around here there are only 2 digits past
the mhz. IE: 132.27, 132.77, etc. Many times they will just spit out
32.77 as a readback.. Pilots and controllers always look for a
shortcut around here as it's busy. IE: "contact ground point niner"
They don't even bother with the mhz. Most of the ground controls are
on 121. -7,8,9. The controllers will love this new bandplan...
Not! :/ MK

The halfwave will work fine. You don't need the radial thingys though.
All you need is a 1/2 wave vertical, wire or tubing, and a single turn
gamma loop match at the base. I could tell you the dia and cap needed,
but I'd need to know the freq. Actually, I could get you fairly close
by giving you the 10m specs, which are about 11 inches dia coil, and
about 50 pf worth of cap. I make the caps from coax. Just take those
specs and double for 20m, 4 times for 40m, etc. I use one of these on
10m with no radials at all, and it does quite well at only 20 ft up. I
make the coils from soft 3/8 inch copper tubing usually. MK

Hi, Peter,

The Qwest/USWest pre-standard VDSL systems
in Phoenix are made by NLC using Broadcom QAM chips.
I don't believe they had/have the ham band notches.

I'm looking forward to your cable programs.
I have been contemplating writing my own,
but if I can steal them...
I _really_ do miss UNICCAP. [R.I.P. :( ]
The project was in my Bell Labs organization in WH.
I dug out the 26-year old manual last week
to look some model info.

73,
Ron

I had a GAP titan that went together well, had a decent match on all advertised bands and performed very poorly compared to most antennas I have used. My bad experience is from direct A-B comparisons with a Titan and several other types of antennas. There is a lot of info and postings about this topic and a google group search will flood your computer with GAP testimonials. From what I can tell most of the praises come from users who have not compared the GAP to anything else.

Now I recall that particular movie.
It involved a Ham operator that the by made friends with, and after the Ham
died, I think, the boy tried using the equipment.
But it's been a number of years since I saw that one.

The March/April issue of QEX has an article on a grounded half wave
vertical antenna. You might want to take a look at it.

The article talks about the problems with the typical half wave
vertical and proposes a solution. I wouldn't mind trying it on 30 Mtr
my self.

I hear that some women believe its proportional to
the difficulty of getting on top.

I'm mildly curious why you typed "special splitter" instead of the more
direct and informative "FM/TV splitter", which he could buy at ratshack?

According to my dictionary, there's no such word as "aluminium."

But it does have:

aluminum

aluminum (e-l¡´me-nem) noun Symbol Al
A silvery-white, ductile metallic element, the most abundant in the
earth's crust but found only in combination, chiefly in bauxite. Having
good conductive and thermal properties, it is used to form many hard,
light, corrosion-resistant alloys. Atomic number 13; atomic weight
26.98; melting point 660.2°C; boiling point 2,467°C; specific gravity
2.69; valence 3.

[alumin(a) + -(i)um.]

There are small spiders which migrate at certain times of the year in some areas of the country (including yours) which actually ride the wind on their own web material they spin for just that purpose. They are "intercepted" by your antenna system, and then they look for a place to make a den. What they find is the weep holes in the bottoms of your traps. They go inside, make themselves at home, spin more web material inside the trap housing and set up housekeeping. The material that looks like grass is spider web.
None of that would probably matter much, except for the humidity in the air, which will condense on the web material with lowering temperature changes, and leave the web that is nestled around your trap coils and insulators saturated with moisture. Inside the trap housing, where it is well enclosed, it will dry very slowly, and probably not completely until hot weather.
Then, before it has the necessary time to dry, contest time comes, and you fire up the amp, pump big watts into the antenna, the high voltage finds the damp web material, and -
Flash! You have seen the results.
Is there a good solution? I don't know, but if I ever rebuild another trap I think I'll try to glue some fiberglass screen over the weep holes inside the housing before reassembly to keep the lil buggars out. I'm not sure one could then fit the cover over the inner works without removing the screening- those things fit together pretty tightly.. Might be best to epoxy small pieces of aluminum screen over the holes on the outside of the housing. Looks ugly but should keep things clean inside.

I learned about all this while rebuilding an old Mosley TA33 about 30 years ago.

The umlaut over the ö can be written in many ways, as two dots,
as a wavy line over the o, or as two leaning vertical short
lines.

The wavy line is how I write it when I write by hand.
Sometimes I write the leaning short lines, with some pens and on
some surfaces.
The two dots is the most common way to write it in printing and
in the windows character table. That is how I write in on the
computer.

But the ways to write the umlaut changes nothing in the
pronounciation, it is still the same letter and the same sound.

KA9CAR wrote:
"---force me down to 30 and 40 within a couple of years."

Without radials, an unbalanced antenna needs some other "ground", car body, rod, water pipes, etc.

A 40-meter dipole would need about 65 feet for resonance. It can be loaded or resonated if it must be shorter. Short vertical dipoles work as short horizontal dipoles work. But, an end-fed antenna is fed against ground.

A balanced vertical antenna is center-fed.

The ARRL "Antenna Book", 19th edition, chapter 6, on: "Low Frequency Antennas" is a good reference. Look at loop skywires in chapter 5, too.

Best regards, Richard Harrison, KB5WZI

I saw "Frequency" on TV last week.
Complete rubbish!
No QRN / QRM. No PTT, Full duplex, and only one throwaway mention of the need to have licence, callsign etc.
NOT a good advert for ham radio at all!

There is fairly good Australian factual drama that was on South African TV about 10 years ago called "Cyclone Tracy". The story of how the Northern Territory capital, Darwin, was practically wiped out by a cyclone that was "not supposed to be there" on Christmas day in 1974. The only ham in town managed to rig up a random wire in the wreckage and call for help.

I was always amazed at the way some HAMs tried to hop on the
bandwagon as if Frequency was a big PR for HAM radio...

Anyway... Some time ago there was an old movie I saw, and I think
it was one of the early 'docudrama' type things. About WWII and
the bomb. Had to do with a HAM that was made suspect because
radio signals were coming from his neighborhood... The film was old
black and white, and looked to be made in the 40's, just after the war.
Didn't have that '50's feel' you get from movies starting about 51 or
so when TV was poised to start expanding.

I am also curious as to why you reccomend staying away from foam filled twin lead. I used it for a few years, and was dissapointed when I could not find it this time. It was easier to work with, and stiffer than the simple pvc type.

I would not use the foam filled twin lead that has a foil shield, although I have not seen that product in a few years.

My EE advisor at the University of Washington worked at Bell Labs in
the mid 1960's when Bode was still alive. He told me that Bode
pronounced his own name "Bowdee", with the "bow" syllable pronounced
as in "bow and arrow" rather than as in "bow of a ship".

Right you are. I didn't realize that "Original" was also a link. It is crystal clear, and interesting, too.

Thanks also to Tongaloa for emailing a response to me directly, to let me know that "Original" is the
link to click.

Interesting way to get such low angle radiation. An 80 dipole would have to be up a couple of hundred
feet to radiate that low. I'll bet it's quiet, too.

What John has not made clear is that what he means by his
approximation '"', is that the 'o' in Erdos has what looks like the
double quote character above the 'o', rather than two dots. I'm
looking at an article in "The Mathematical Intelligencer" for Spring
1997 titled "A Remembrance of Paul Erdos". The diacritical mark over
the 'o' looks like a double quote which is leaning, as though it were
italicized.

I like your idea of using soft 1/4 inch copper for the base coil.

The idea with the radials at the top (often reffered to as a capacity hat) is to reduce the hieght of the antenna while keeping it resonant. As my trees have a usable hieght of only 30 feet high I need a top hat. Since the trees are less than 20 feet wide at the top, I will still be short of resonant length as the radials will be less than 10 feet each. By adding coils I should be able to bring the system in to resonance. Putting the coils near the ends of the radials instead of on the vertical wires, will keep the I^2R losses in the coils low as the coils will be as far as I can get them from the current maxima.

I've pulled a couple out this way: The top of the ground rod is usually
a bit flattened from pounding it into the ground. Put a decent sized
ground rod clamp on the rod near the top, and use an automobile jack
between the clamp and ground to raise the rod. If the rod is too short,
just dig away some soil until the jack fits. You can also wrap a heavy
chain around the rod below the clamp, and then wrap that around the
jack. They come out pretty easily that way.

Uhm... the movie was meant to be a paid advertisement for ham radio just as much as Apocalypse Now is supposed to be an ad for joining the US Army.

As for full duplex - that's Hollywood for you. In their world cars start without keys, no one closes the door behind him, automatic machine gun fire misses the lead actor from five feet, people always enter dark areas when chased by a killer, spilling coffee on keyboards causes nuclear meltdowns, and so on...

Do you have the necessary matching coil at the base? Believe it or not,
the higher the SWR on 80m mobile, the better is the mobile antenna. The
feedpoint impedance of a good 80m mobile antenna is 12.5 ohms yielding
an SWR of 4:1. The feedpoint impedance of your Hamstick appears to be
about 20 ohms. You can use a base coil, or base cap, or base UNUN to
accomplish the necessary impedance matching at the base.

4798. vertical antenna opinions

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-08 21:08:10 UTC
From: AB Brown <abbrown@nospammail.com>
Message-ID: <a6b96l$g2l$1@slb6.atl.mindspring.net>
Source record: 146983

I would like to install a vertical antenna for 20-80 meters. Due to space and antenna restrictions, I am going to have to construct the antenna from copper wire. Here's a description of my antenna installation plans:

My yard contains two 40-45 foot pine trees spaced about 10 feet apart. I am going to vertically attach a wire between the trees of about 35 feet in length, which I hope will serve as the vertical part of the antenna. At the 40-45 foot level, I may stretch a horizontal wire between the pines of about 10 feet in length to serve as a tophat. The vertical may only be 35 feet because I'd like to attach 4 elevated 8 foot high ground radial wires to the base. Of course, at the base of the antenna will be a variable pi network to match to 50 ohm coax to the antenna and allow all band operation.

Opinions on my plan? Is a slightly shorter vertical with elevated radials better than a longer vertical with ground radials? How about the 10 foot top hat?

Thanks, in advance.

AB

Reg, even the 80m Hamstick requires some impedance matching at the base.

Hello George

I guess I used the term "special" so someone with little technical
experience
wouldn't be tempted to use a more common VHF/UHF type. It sounded like
it was using 300-ohm TV twinlead from his discription. If he is using
75-ohm
cable I would have suggested using a run-of-the-mill hybrid CATV splitter.

From: me@nowwhere.com
Message-ID: <3C894730.1DBB5856@swbell.net>
Source record: 146991

hi

i live in the dallas tx metro area and the
ground around here leaves a lot to be desired
to say the least. in addition, i live on a very small
city lot where it is easier to install things vertically
so i've been playing with the idea of sinking
a vertical shaft 15 - 20 feet deep, and then inserting
a 3 - 4 inch well caseing that has had the bottom
end plugged up and then filling it with water and
using it for a ground.

intended bands of operation will be 40, 80, 160 meters
using a base loaded vertical with capacitance hats.

how good a ground would it be? good, bad, indifferent?

any help appreciated.

Great! It looks like a good movie, though. You can't really expect these
Hollywood writers to get everything right, but you'd think they'd research
the background info better, huh?

Totally normal. In fact, it's a good sign. That means the coil is not overly lossy for a hamstick. NO mobile antenna for 80m will show a good SWR if it's any kind of decent antenna at all. You will need an impedance matching device. They sell them, or you could use a simple tuner. Also a tapped coil would work. IE: "dollar special" that is in the ARRL ant handbook. MK

Larry,
It won't be a very good ground considering the
trouble you'd have to go to to put it in. You'd
be much better off to put in radials, till you just
can't stand the thought of 'doing' one more! Then,
put in a few more just 'because'. 'Deep' doesn't
necessarily mean 'good' as a ground...
'Doc

I don't know about the windings, but I've used black 3m weatherstrip
adhesive to patch cracks in the black plastic covers. I don't know how
that would work over windings... MK

4812. antenna am...

Bonsoir,
Petite question technique am : une petite asso (sans gros moyens financiers) en France veut monter une radio locale am pour couvrir le village et alentour (port&#65533; de 5 &#65533; 10Kms max). Leur but est de cr&#65533;er une radio locale d'infos de proximit&#65533;, d'expressions locales et musicale...
Questions :
- qu'elle type d'antenne utiliser : Levy, Marconi ou autres filaires pour un emetteur de 30 watts ? ou les envoyer pour trouver les plans de ces antennes ?
- ou peuvent-ils trouver une boite d'accord pour cette bande radio am (522 &#65533; 1611Khz) ?
- et enfin ou peuvent t-ils trouver un petit ampli de 100 &#65533; 500 watts am ?

Greetings. Thank you all for your informative posts. I have been reading this group since getting licensed last March and have learned very much. Now I need some specific information/opinions.

I have a TH6-DXX in pieces in the garage and will be acquiring what appears to be a Rohn 20 tower (my foot barely fits in it to climb) - 30 feet. I plan on mounting the tower next to the one story garage and bracket it for support. Will the tower safely support the TH6? There is a home-brew 3-element beam on it now that looks about 1/2 to 2/3's the size of the TH6. Optimally, what height should the TH6 be? In other words, is 30 feet too low to the ground? Finally, what rotor do you recommend for the TH6?

AH HA!

NOW ve are getting zomewhar. Seriously, you are trying to apply the portability of VHF
to HF. The two are entirely differently animals. You will need to ditch the mag mount for
80 meters. Get some sort of permanent mount that will exhibit a ground, then check the
SWR without any impedance device. If it works, or loads up, then you won't need any
further work. If not, you need to use a coil , capacitor, or toroid at the feed point. I am
not disparaging your knowledge of mobile radio, but it seems you need to avail yourself
of ARRL's handbook or antenna books to learn more about the workings of mobile in-
stallations.

One thing further about 75 meter hamsticks--they are usually "sucky" on that band. Look
at it this way: if you turn on a garden hose and let it run without a nozzle, it will run quite
freely. Stop up the end with your thumb, and the pressure increases inside the hose. This
"pressure" in an antenna is comparable to the stopped-up hose and is that SWR you are
seeing. The ham stick is a small form with small wire tightly wound around it. When those
little "electrons" of RF start trying to travel up that narrow "road" (itsy bitsy wire) and get
around those tight "curves" (coil windings). The road is so crowded and crooked, and all
those millions of RF electrons are in a traffic jam, they get "road rage", and all hot and bothered. The result is signal lost as heat. There is, of course, more to the equation than
this, but I didn't intend to write a book on the subject. You will learn much on this as you
go--that's the way I did and everybody else, too.

Just remember one thing: If you are serious about having a good 75 meter HF mobile, it
takes a BIG UGLY antenna! Along with some grounding and a few other tricks. You
can have "Pretty", or you can have "Performance"--but, unfortunately, you can't have both.

It's the way it is.

Besides bracketing, you should consider guying the tower from the top
of the top section.

I could barely fit a TailTwister in my Rohn 20 flat-top top section. Have
you considered that you will not be able to mount the rotor in a Rohn 20
so it will have the benefit of a sleeve or thrust bearing to abate lateral
stresses on the rotor? I wouldn't top mount any rotor with a TH6-DXX
for a load.

30 feet is a bit low for a tribander, for 20-meters I'd go at least 50
feet,
or even 40. 30 will work, but higher is better.

IMHO, there is no bargain in a free tower that is not up to the task. I'd
go with at least Rohn 25, properly guyed and bracketed.

Pete

Thanks for your advice. The top is pointed instead of flat. Maybe
I'll just install a 2-meter j-pole on top of it, hoist a G5RV from it,
and keep searching for Rohn 25.

Monte

That's because it is an American dictionary. Other than the US and Canada, the entire world spells it aluminium, which was also what the element's original name at the time of its discovery was, and is a spelling that adheres to the traditional "ium" ending on most metals.

Our mis-spelling of it is puzzling since most metals on the periodic table end in "ium". For example there is no such thing as Thorum; it's Thorium. Similarly Uranum, Plutonum, Calcum, Strontum, Lithum, Sodum, Potassum and so on don't exist, They all end in "ium". Somehow, we in North America persist in misspelling "aluminium" as "aluminum"! No doubt this was another one of Webster's numerous spelling changes to demonstrate that the US was no longer tied to Britain.

I have a 90 foot vertical with four 30 foot top hat wires spaced
90 degrees and sloping downward at 45 degrees. It resonates
as a current fed vertical on 160 meters. It also resonates as a
voltage fed vertical on 80 meters. In that mode, you need virtually
nothing in the way of ground radials. You could scale this design
to 40 meters: 45 feet high with 15 foot top hat wires. 45 feet
of aluminum tubing is very easy to walk up.

There's been a lot of 25 showing up here in Texas lately. A lot of small dispatch radio system operators are changing to leased trunking, or cellphones, and a lot of 50 to 200 foot towers are coming down. Find a two-way shop and inquire. Try several, and don't be surprised if some are downright obnoxious.

4828. UHF PCB Antenna design questions

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-09 04:28:18 UTC
From: Doug Dougherty <minerva@mindspring.com>
Message-ID: <3C898F62.5422D168@mindspring.com>
Source record: 147013

I need a small PCB antenna for a short-range, 900 MHz ISM-band application. The design calls for a small (1.5") circuit with components at the center of the board, and an antenna trace running around its periphery. I don't know much about antennas, but I understand there are 3 types that are best suited for this application: a quarter-wave stub, a loop, and a semi-loop.

My board is too small for a straight quarter-wave stub, so if I went this route, I'd have to curl the stub around in an almost complete circle. Would such an antenna radiate well? Would it be susceptible to hand effects?

If I use a loop antenna, can I loop a quarter-wave trace around the top of the PCB, with a via connecting to a second turn looped around the bottom of the PCB? I understand that the larger the loop, the better the radiation resistance. Does this apply to multiple turns as well? Can anyone tell me what the pattern would look like for a multiple-turn, quarter-wave loop antenna? The only patterns I can find are for so-called "small loop" antennas.

Finally, I read of a "semi-loop" antenna that consists of one loop around the top of the PCB, with a via at the far end connected to a short trace on the bottom of the PCB. The short trace on the bottom of the PCB forms a series capacitance with the loop on the top, and the length of its overlap is tuned for resonance. This antenna is supposed to be very good at rejecting hand effects, but I can't find much information on it. The only thing I can find says that the circumference of the PCB needs to be well under one-quarter wavelength, but I don't understand why. Is anyone familiar with this type of antenna?

Which of these 3 antenna types would be best for this application? Any help or useful references would be greatly appreciated.

Doug Dougherty

Sorry if it is a "major problem". Use an antenna tuner if you don't want
to install a coil or cap at the base. You probably should not be using
a mag mount on 80m - not enough capacitance to the body of the vehicle.

I take issue with that statement, Jerry. I have a big, beautiful antenna
and it works great on 75m. The antenna is the best looking thing about
my truck.

For short distances anything with a perimeter of 1/5-wavelength or longer
will work well.

But most definitely do NOT use multiple turns.

That's a good general rule (labor/labour, zee/zed, center/centre),
although it's slowly becoming less so (color, for example).

It just happens to lead to a completely incorrect conclusion in this case.

I need help picking the best 6 meter vertical antenna.
I think I have narrowed it down to:
Hy-Gain V-6R
Diamond DP-GH62

Has anyone ever used these two antennas and if so wich are the best in
radiation, gain, and quality.

THANX!

Monte..

Be careful buying used tower. Examine the galvanizing, it should be
clean of rust. Use a flashlight and examine inside of the legs -- towers
can rust from the inside out, which makes used towers very dangerous
to take down.

New Rohn 25 runs around 90 bucks a section. I bought a 65 foot
25 foldover with rotor for 400 bucks. Price seems to vary by region,
condition, and the amount of tower on the ground in that area--but
it shouldn't be expensive.

I tell ya what. I'm sure the Hy-Gain and the Diamond do is very nice job. I used a Lakeview Colinear several years ago on 6, with VERY good results. It is very inexpensive too! Non of these do as well as a good beam or quad, but for the money, the Lakeview did an excellent job! http://www.hamstick.com/

Trying to find the tensil properties of 18ga stranded copper. I lost
my Dipole suppoer (70ft Hemlock) to root rot (had to have it cut down)
so now Im sans my 80m antenna. I bought some new 18ga stranded copper

to hang up. My idea is to use my front tree (35ft) and a 20 ft mast
in back to yank a dipole up. RG214 would tie to a center plastic
hold.

Would 18 ga yank up the coax and survive or would rope be needed
acrorss the span.

Unfortunately my meager 25ft tower wouldnt suffice for a good center
support (would only have 20ft for center hold)

Any other suggestions would be appreciated.

Just based on gut feel, I don't think it would be anywhere close to
strong enough for survival. I've got some jacketed 18 stranded hookup
wire and I can tie it to something and break it by hand.

Over time I've seen several references to electric fence conductor used for
wire
antennas. I've seen it and it's basically fiberglass or some such material
with just enough wire in it to be a conductor. It might just be that this
stuff would do what you are
trying to do. I think it's available in cord or tape form. Those advocating
its use say it's reasonably priced also. (Don't go by me, though, I'm still
waiting to take my license exam and my expertise is limited)

The hell we do! I am a Canadian, and have never seen it spelled "Aluminium"
here in Canada, and among other things I have worked with aluminum extruders
for 25 years. In Canada, we use the corrupted American spelling ("Aliminum")
and the American pronounciation as well.

I wouldn't pay more than $20 a section for it unless it is almost new.
Sometimes it is available for the removal, but follow the advice from Rohn
and others about rust, weak spots, and temporary guy wires if you want to
take some down. BTW, I have 100 feet of 25 which is in its second location
and was originally erected by me in 1962. I have replaced most of the joint
hardware due to rust, and touched up a lot of spots on other places,
especially the cable clamps on the guys before I replaced them with
preformed grips, but the tower itself shows no rust on the outside, and
sounds solid still at the point it leaves the cement base. I worry about
the anchor rods and examine them regularly, but they are holding their
galvanizing well also.

Rick

My suggestion would be to go the WireMan and get the proper antenna
wire to use. It isn' that expensive, and why worry about using something
not intended for the task at hand?

A ham 4 works fine.The tower I'm worried about,how much of the tower will be above the top bracket? I had a TH6 with a similar tower which was bracketed to 20' then the tower extended another 30' and was guyed from the top (2 guys were to the roof) using torque arms. That long boom will really want to twist things.The tH6 will work better a little higher but is a great antenna,I replaced mine with a 2element 5 band lightning bolt quad. A similar quad WOULD work on your tower FB.TG

A quick search for "hungarian umlaut" with Google convinces me that
John is right. See for instance:
http://www.oakland.edu/~grossman/readme.html
where it is said:
"Most practicing mathematicians are familiar with the definition of
oneï¿½s Erdï¿½s number [that is actually a long Hungarian umlaut over the
ï¿½oï¿½ but we will represent it here by the ordinary two-dot umlaut
available in html]."

Also see:
http://www.hungary.com/hungq/no157/046.html
where we find:

Thus tï¿½r is "to break" but tï¿½r is "dagger".

It seems that there are indeed two different umlauts in Hungarian; so
different that they affect not only pronunciation, but also meaning.

Source record: 146944

The higher frequencies are more forgiving than 75 meters and, generally speaking, "natural"
impedances exhibited by such antennas are usually higher. For example, look at the many
mag mounted CB antennas. But as you go downwards in frequency, if the antenna is rea-
sonably efficient, the impedance tends to go downward, too, so you have to add a little
"help" to bring this figure back up to 50 ohms. Remember: on 75 meters you are trying to
squeeze 120 feet of wire into a form less than 10-12 feet, whereas, on the higher bands,
the amount of "crunching" of wire down to a manageable size is not nearly so huge.

Here is something else to remember about operating on 40 and 75: any antenna that doesn't
require some sort of impedance matching at those bands and lower is a sloppy, wasteful ra-
diator. Here's why: That signal that you are now asking to sacrifice a nice long dipole and
travel reliably and. hopefully, loudly, is now scrunched down into some sort of antenna of
9 feet or so. In doing this, the signal encounters 3 resistances; feedpoint (impedance), coil,
and radiation resistance. Remember that in our last exchange, I told you that, in small dia-
meter coils wound with skinny wire, the RF electrons get into a "traffic" jam. So, let's say
that your hamstick is exhibiting a feedpoint impedance of 17 ohms (it should), a coil resis-
tance of 20 ohms, and a radiation resistance of 13 ohms (tho I doubt it would be exactly
those figures--I'm just using them to prove a point) Guess what! The total adds up to 50
ohms--just what the radio wants to see! So, why doesn't the stick operate well as is? Be-
cause the equation is upside down! Most of the resistance in the system is up in the loading
coil where that "traffic" jam is pissing off all those little electrons! With an efficient antenna
like a screwdriver, or a large inductor coil antenna, the resistance now drops in the coil so
that the 50 ohms is no longer there. Why? You widened the "road" by making

the curves
less tight, and the wire larger so it can handle more RF, they don't "get mad" at each other,
and "traffic" moves right along. But to make the radio happy as well, you have to add some
sort of impedance matching device at the feedpoint to bring that 17 ohms up to a figure that
will again allow the individual resistances to add up to 50 ohms.

I suspect that your trouble has more to do with the lack of ground due to the mag mount.
The antenna is decoupled from the other half which is the vehicle. Look at it as if it were
a kind of dipole, or inverted "L"--which, in a sense, it is. The radio is "seeing" only half of
the antenna because the shield is not terminated.

I suspect that, if you ditch the mag mount, and attach a permanent mount to the bumper or
trunk or deck, the antenna will resonate, after pruning, on 75 meters. But, because of the
nature of hamsticks, your results will not be exactly stellar. They will, however, work pretty
well above 40 meters. Some people are quite satisfied with hamsticks and brag on their
results. I can't help but wonder--compared to what? But to each his own, and if the hamstick is what one must use, then that is fine. I just prefer to be heard the first time I call.

Best 73, and I hope I have helped.

My "Oxford Canadian Dictionary" gives the "um" form as the main form and the
"ium" form as secondary (preceded by "Brit.")
As a Canadian, I spell and say "aluminum" (agreeing with the
dictionary)but understand "aluminium" which ex- Brits use. Some of our usage
is as in the US and some as in britain (i.e. colour,etc)

Maybe this will help, Jerry. Here's the radiation resistance of an 8ft
center-loaded whip Vs frequency according to the ARRL Antenna Book.

1.8 MHz 0.2 ohms Perfect SWR = 50/0.2 = 250:1
3.8 MHz 0.8 ohms Perfect SWR = 50/0.8 = 62.5:1
7.2 Mhz 3.0 ohms Perfect SWR = 50/3 = 17:1
14.2 MHz 5.8 ohms Perfect SWR = 50/5.8 = 9:1
21.25 MHz 27 ohms Perfect SWR = 50/27 = 1.9:1

Of course, we cannot get that perfect SWR because there are around
10 ohms of ground losses. That 10 ohms of ground losses are about
93% of the signal on 75m but are only about 27% of the signal
on 15m and even less on 10m.

Moral: The higher the SWR on 75m, the better the antenna. My
screwdriver has an SWR of 4:1 without base matching. Of course,
it is the 12.5 ohm feedpoint impedance that is desired, not
the other possibility, a 200 ohm feedpoint impedance. :-)

Young whipper snapper! Heh, heh... Bob it so happens that I am a
naturalized American. But...

I was born and educated in Canada. I completed all of my schooling in
Candaa, without stating my age I'll say that I finished K-12 somewhat before
the fifties ended. My experience was varied as well: e.g. K-4 in Nova
Scotia, 5-9 in British Columbia, 10-13 in Ontario, etc... It so happens that
at the many Canadian schools that I attended in that era, we exclusively
used the OED in all the schools that I attended. And I was definitely
taught to spell the element Al as aluminium! (Oxford English Dictionary).

These days, even though I have been living in the USA for years and I am now
a US citizen, I still find myself spelling the OED way!

Only the spell-checker in MS Word keeps others from learning of my spelling
heritage, heh, heh...

All the Rohn 20 cost was about two hours of labor taking it down and getting it home. And I got a three element beam, a rotor, and a tilt base with it. But, just as important, was the time spent with an old ham (he helped), and the start of a good friendship. He got out of Amateur Radio years ago and is happy to see the tower put back in service. Over the next few weeks I'll clean it up, replace what's necessary and get it back in the air. I'll bake some pies (my other hobby) for him and his wife, too.

There is some minor rust, and the bolts between the sections will be replaced. What's your suggestion on dealing with rust?

Monte

Ed:

I don't know, does MS have a Canadian English preference for its' spell checker as opposed to a British English preference? I have never checked for this option? If one is a Canadian Anglophone, how does one set their preference on the MS Word spell checker?

Is there now an official Canadian Standard English Dictionary? If so can you share with us what it is? The British have their venerable OED, which used to be the "official" Canadian dictionary back when I was a child in Canada. I was taught from the OED during my whole Canadian education. There was always an OED in every Canadian classroom when I was a child!

We Americans have our Daniel Webster, and of course the MS spell checker, which I currently have set to correct me as I type, but... what do the Canadian Anglophones have today? Heh, heh... I haven't thougt about it in years, but... do (poor downtrodden) Anglophone Canadians even have an official dictionary these days?

BTW... I presume you know that there is a Quebec French preference on spell checkers, as opposed to a Parisian French preference, etc... and indeed many software products are customized specifically for Quebec French, occasionally including some hardware items like keyboards, that customization effort is a small "cottage" industry in some parts of Quebec, but...

I still wonder... are Canadian English speakers now so honored (or is it honoured sic? Ooops... MS's spell checker just tried to over-ride that last instance of hono(u)red!) as to have their own official dictionary and not one borrowed either from the British or the New World Revolutionists?

Actually, according to charts, the Dallas area is better ground cdx
than many other places. You are in a belt of good ground that extends
from Texas up into Kansas, Neb, etc. The well case ground would not be
near as good as a set of radials. MK

A single thin piece of wire at the top, especially if it goes in just one direction from the top insulator won't act as much of a top hat but rather as a folded inverted L. Especially if a physically short vertical there will be high voltage at the top of the wire, you need some surface area to dissipate it to prevent it from burning the insulation.

What I have used in the past is to terminate the top end of the antenna on a small piece of copper pipe - can use 3/8" if using under 250 watts, "½" if running 1 KW. It need not be more than 6" in length. Solder the wire to the copper pipe. Sweat a threaded male connector to the top of the pipe. Place the connector into a piece into a female threaded piece of PVC. Connect a PVC "T" to the threaded connector with the bottom of the "T" having the threaded female connector. Place PVC end caps on the "T". You now have a mechanically good insulator/support for the vertical element which will dissipate the current.
Drill a hole in each PVC cap and string a nylon rope through the horizontal portion of the "T"
Tie each end to the each tree respectively.

Use as long a vertical element as you can. A shortened helically wound vertical will transmit just fine but you will not capture much signal and you will be disappointed in what you will receive. The shorter the antenna the narrower the bandwidth will be around the resonant frequency.

Elevated radials will perform better than grounded ones. Use at least 4, 8 or 16 would be better. They can be very thin wire (even #22), it won't matter. If they are up 8 feet they'll be largely invisible. Try to make them 10% longer than the antenna length if you have the room.

Best of luck
Richard W9EEE

[Snip]

Actually, that is rather interesting to me. All through my school years in
Vancouver (I graduated High School in 1963), not once were we expected to
use the correct (i.e. English and the rest of the world's) spelling of
Aluminum (that is, to spell it Aluminium). I recall once or twice it was
mentioned in passing as something that "they do in England", but that was
all. From what you say, it appears that there were varying "standards" on
this in different parts of Canada. Interesting.

Bob.

Please don't take it personally. I admit to unjustified exaggeration when I said "everybody's" time.

But the necessity to read through contributions, before realising time has in fact been wasted, will be appreciated.

It is tedious on occasions to read through long lists of references to books, papers, articles and authors who 99% of readers have never heard of, or at least have little hope of ever obtaing access to, or will never have the time to search for, issued by contributers of this newsgroup who feel insecure and are in need of moral support for their statements from obscure, remote sources.

The only conclusion to be drawn is that some contributers are at least very widely read and have immediate access to extensive libraries, sound factual technical contributions being effectively nil.

But engineering, a hobby or not, does not consist of reading ill-understood books.

Nevertheless, many contributers, including myself, obviously obtain entertainment and satisfaction from this particular newsgroup's many topics and activities.

Reg

"Canadian Oxford Dictionary" It's pretty good- includes such things as
qiviut, etc. Spelling is colour, honour, etc but also aluminum (one I)-
however the variants color, honor are also listed.
I am close to your age) but in Alberta, we tended to use color, etc -less
enamoured with the old country than Ontario or BC.
I just checked my MS Word- it does have a variety of English settings,
including "Canadian" but this appears to be more British (aluminium for
example)

Just looking at Alcan's history- it's interesting- they started as a subsidiary of Alcoa, got divested in 1928 as the _Aluminum_ company of Canada, and then in 1982 merged with the British Aluminium Company plc (as well as buying US aluminum assets of Atlantic Richfield) became Alcan _Aluminium_ Limited. In 2000 they merged with Alusuisse Group Ltd. to become just Alcan Inc., which would seem to solve the problem (for now).

I feel that "performance" is subjective. I really like my Titan because it's a no-fuss antenna. I agree that it may not pull in the signals as well as some other bits of wire, but it sure is convenient to be able to jump from band to band without having to switch antennas.

I have a 2-el 17 meter mini-beam and a 20 meter dipole also. I find the dipole sometimes works better when the signals are broadside to it, but the Titan fills in for stations off the ends. Same-o for the mini-beam. It's got an Armstrong rotator, so if it doesn't happen to be pointing in the right direction, I can switch over to the Titan.

I had a bunch of wires strung up all over the place before I got the Titan. The XYL was not at all pleased. After putting the Titan up on an out of the way spot on our lot, the home is much happier.

And lastly, I'm a just rag chewer. The Titan fills the bill just fine for that. If you're looking for serious performance, you're not talking about single-element verticals and dipoles anymore. I can't say that the Titan is the best all-band vertical as far as performance, but it does a great job for what I want out of QSOing.

From: JRW <freeboy@ic24.net>
Message-ID: <u8mk50bv1g21b2@corp.supernews.com>
Source record: 146966

Hi all,

If I transmit voice on 18.165MHz it can be heard on 1117kHz-ish. Also if I try other frequencies the same happens. The MW receivers are mains powered and are in the same house. My antenna feeder (RG58) goes through one room, and up into the attic. Could the cause of this phenomenon be RF in the mains? A battery powered MW receiver on the same frequency did not receive my signal, but, I don't know if that radio was selective enough.

BTW The transmission is USB, and is 10W PEP. If I transmit SSTV then only the radio nearest the feed receives the signal, but on voice all radios receive the signal.

Any suggestions appreciated,

also,

What is the impedence of the balanced feeder connection on the Palstar AT300LCN ATU?

TNX

==========

Chipcon AS's application note is about the best quantitative summary of performance of short, low-profile, antennas I have come across.

Although writen for UHF applications it is also applicable to HF antennas used in restricted environments.

I need help in finding a collar adapter that will combine two sections of a stainless steel whip antenna. I need to cut a whip in half for easy transport. I know I have seen them at ham fests but can not find a vendor today.

The collar is about an inch long with hex set screws or thumb screws to lock in both sides of the whip. The whip diameter is about 1/8".

Thanks for any help.

A while back I took my ScrewDriver antenna off my full size 96 Extended cab GMC truck. This weekend we had super high winds and I was going to try to work some of the Great Lakes QSO Party. The antenna all ways worked fine no matter where I tuned it. I picked it up at Dayton last year from a guy with a 9 call, I think from Ill. I forgot his website URL but it was something like amatuerantennas.com or something close. Now I can't get it to tune on 10,12,15,17 at all the radio just got nuts. It will sometimes tune on 20 meters. It always tunes on 30,40, and 75 without any problems. I am using an Heathkit SB-1400 with an MFJ tuner set for direct only so that I can see the SWR meter on it. I also tried my icom 746 with the same results. I have a 54" whip on the top, and have been using it right along....

Any one have any ideas for me? I even took a pop can and put 4 loops around it with the coax incase I had some RF feedback. Yes, before someone asksI made sure it was grounded so that the matching unit was working.

Thanks very much Reg and Tom. That is the best application note I have seen for these antennas.

Reg, why not use multiple turns in a loop antenna? Would that change the radiation pattern from radial to perpendicular to the plane of the loop?

Most mobile hams solve the matching problem with a coil or cap
to ground at the antenna base. It might work if you attach the
coil from the base of the antenna to the base of your mag mount.

there are lots of possibilities. it could be just plain front end overload, rf on the ac mains, an IF leak in the transmitter, bad image rejection in the receiver, mixing with some other signal nearby, or any combination of the above. i would start by putting a filter on the ac cord for that radio. then check for overload by removing the rx antenna or inserting an attenuator. after that there are various combinations of IF leaks or image frequencies, which most of the time i would ignore as they are hard to remove and very short range.

btw, sstv would probably be not as noticeable as it is an almost constant amplitude so would appear as a carrier unless you were receiving in ssb.

I agree. First thing to check is the finger stock. Remove the cover (if not clear) and see what is going on when the coil gets down toward the bottom. Same thing happened to me recently. finger stock became unsoldered on one end.

Doug Dougherty asked -
> Reg, why not use multiple turns in a loop antenna? Would that change the
> radiation pattern from radial to perpendicular to the plane of the loop?
==========

If the larger number of turns of thinner pcb track widths are all in the same plane there will be zero effect on the radiation pattern. There are just some amps flowing round the same circle. The pattern is still omnidirectional in the plane of the turns with a null at 90 degrees to that plane.

Now very much reduce the diameter of the turns and stack the turns one above another at right angles to the board. You end up with a 1/4-wave or 1/2-wave continuously-loaded vertical. Also known as a Helical. But the pattern is still omnidirectional in the plane of the turns with a null at 90 degrees.

The reason for NOT using multi-turn transmitting loops is an even lower efficiency than a single turn. The conductor loss resistance increases due to N times the length of more than N times thinner conductors, compounded by proximity effects of close-spaced turns. Radiation resistance fights a losing battle.

The ONLY reason multi-turn receiving loops are used on medium and long waves is because 500,000 pF air-spaced variable tuning capacitors are not available. ;o)

Yours, Reg.

>Lisnaskea, N. Ireland

Hi Paul, whilst any old aerial will work for receiving. You will get
better reception with a directional aerial... same way TV yagis give
better pictures. Of course with a directional aerial you have to know
where to point it... or use a rotator.

What you are trying to do with the CB antenna is a bit of a stretch. A
vertical antenna for 42.5Mhz would not be hard to make from scratch...

Actually if you do a webserach for antennas for the 6m (50Mhz) amateur
band it should be fairly easy to scale them up to 42.5MHz.

A number of textbooks will give constructional plans for 1/4 wave or
even 1/2 wave whips...

Cheers
Ian/MI5AFL, Donaghadee, Northern Ireland.

Not entirely.The original British spelling was Aluminum, but it was changed
to Aluminium by the International Union of Pure and Applied Chemistry, in
order to follow the 'ium' endings of other elements. America also used this
international spelling until 1925, when the American Chemical Society
decided to revert to the original British version. Have no idea why. Hope
that confuses everyone! (G)

Don't use a mag mount. The ATAS-100 antenna must be well grounded at the base.

I used a Diamond trunk lip mount. The antenna does not seem to have a lot of wind resistance but something strong is nice. Be sure to get a good ground at the base.

Don't use an expensive duplexer to get on VHF/UHF. Just get a cheap second antenna for those bands. MFJ has a mag mount VHF/UHF antenna that looks liek a cell phone antenna and sells for about $20. It works just fine. If you try to use the ATAS100 with a duplexer it makes it harder to tune or scan back and forth. You have to listen to the relays in the FT-100D clack every time it goes to VHF or UHF. I am sure the constant work isn't good for them.

Usually with a mag mount I would just use a small tuner at the rig.
The coax will be short and the losses from the mismatch are pretty
low. In fact, I can hardly tell a difference in performance from
matching at the rig or matching at the base of the antenna. The low
bands have a worse mismatch, but the coax losses decrease with freq so
it works out ok. My coax is only about 8 ft long usually either way.
The mfj random wire tuner will work fine for most matches. I think
they also sell matchers made for mobile antennas at quite a few
places. A simple L network is all thats needed to match about
anything. I usually do my matching at the rig most of the time. That
may sound funky to the purists, but it works just fine as long as the
coax is short. It lets me fine tune the match while moving. MK

The losses in 8 ft of coax is enough to lose a 75m shootout. :-)
Since a coil increases its reactance with frequency, that's what
I use with my screwdriver. If I need to remove my top hat for high
frequency operation, I also remove the coil.

Source record: 146896

Hello all,
Several years ago I saw an article on a ham who built an automatic crank up tower lowering system for his crank up tower in one of the ham magazines(can't remember which one). It was activated when the wind speed reached a preset speed and automatically lowered his tower. Does anyone know where I can find that article or a link to his page if he has one? Or if anyone remembers the article and which magazine it was in, that would be just as good.

Thanks
Mitch KJ7JA

Thanks for the info, Craig! I built a glass mount 2m/432 antenna (un-tested yet, too cold outside ;) so I'll try out your suggestion.
Jeff

> Don't use a mag mount. The ATAS-100 antenna must be well grounded at the base.

Reg,

I understand that using more loops with thinner trace widths will increase the resistance of a loop antenna, and your point about interactions between multiple turns is well taken. But won't multiple turns give a loop antenna a higher radiation resistance? It's my understanding that radiation resistance increases exponentially with the size of the loop. Wouldn't two turns of the same current flowing around the same circle, double the magnetic field intensity?

2 - A-99 Antennas. CB/10 meter. These are the ones that RS sold under their own name. Open the box (at least the ones I DID open) and get Antron paperwork. These two are unopened. They are on clearance and sold AS IS. IF you should have any problems, you must contact the manufacturer for parts.

$40 per antenna - shipped

Please reply direct. Thanks.

Wire brush and paint. I use cold galvanizing spray available in numerous
brands at hardware stores and home centers. Others claim that any good
outdoor alkyd enamel works as well, and I am not prepared to argue. Latex
doesn't stop the moisture. Rustoleum used to be the best choice, but it
doesn't sem as good as it used to be. Just get a good coat of paint with no
holes in it. One caution, never use chemical rust cleaners like Naval
Jelly, as various undesirable things happen to the steel. Hydrogen
embrittlement in the case of Naval Jelly.

BTW, how have you identified this as Rohn 20? It hasn't been produced in
many, many years. Because it has little torque strength. If you do put
that big beam on it, be sure to use some sort of torque arms at the rotator
to resist the twist.

The outline of it was first, a tower with an electrical winch, and a wind speed indicator with a comparator which tripped a relay at a preset speed. Relay applied down voltage to the winch.

Recently the FCC issued a preliminary ruling, changing the part 15 limits for emissions from

ground penetrating radars and similar things. Here's a single graphic showing the limits they

propose:

http://www.wavebounce.com/images/UWB%20limits%20prelim%2002Feb.gif

My problem is that the vertical axis of the graph is in dBm. I'm trying to figure out what

meaning this can have when it's plotted vs. frequency. I'm used to seeing plots like this showing

spectral density (dBm/Hz) power levels in dBm obtained by integrating between two frequencies.

For a wideband source, the bandwidth of the measuring device will determine how much power is

detected, centered at any given frequency. Is it possible that the FCC is simply assuming a

bandwidth minimum, like 1MHz, which they do mention in various places in the part 15 rules?

I would appreciate any comments on this --

Email would be nice (please remove the xx in my return address) but I will be checking the ng.

==========

Doug, dump your old wife adviser and switch to a later edition of the R**L Handbook.

You won't find any reference to exponential relationship and loop size in the excellent Chipcon AS application notes.

==========

> Wouldn't two turns of the same current flowing
> around the same circle, double the magnetic field intensity?

==========

Indeed it would.

But the trouble is, the ONLY way of doubling the radiated field intensity external to the antenna is to increase the power output from the transmitter. That's cheating. Think about it. It has little to do with what the antenna might consist of.

It should be obvious, for the same power input to a multi-turn antenna, the circulating current in each turn must decrease. The feedpoint input impedance to the loop increases as the square of the number of turns.

As I said, the radiation resistance fights a losing battle with antenna loss resistance.

But in your case, it hardly matters. For a range of a few hundred yards? and with a few milliwatts Tx power almost anything will work.

Yours, Reg.

Another "miracle" antenna and bunch of CB type crapola like:

"The most important design point about the CobWebb is that it is a completely horizontally polarised, confined electric field antenna, which provides maximum radiation efficiency and the absolute minimum of interference problems. "

Right up there with Freaktennas.

Yuri

Amateur Radio Newsline™ Report 1282 – March 8, 2002

Amateur Radio Newsline report number 1282 with a release date of
Friday, March 8th, 2002 to follow in 5-4-3-2-1.

The following is a Q-S-T.

The Dayton Hamvention announces the EMMY AND OSCARS of Amateur Radio. We have the winners on Amateur Radio Newsline report number 1282 coming your war right now.

(Billboard Cart Here)

**

HAMVENTION 2002: AWARD WINNERS NAMED

The Dayton Hamvention has named Radio Amateur Information Network founder Alanson “Hap” Holly, KC9RP, as its 2002 Radio Amateur of the Year. Holly received the news of his selection on Thursday evening February 28th in a phone call from Cathi Hoskins, N8ZCQ, who chairs the Hamvention Awards and Banquet Committee. KC9RP tells Amateur Radio Newsline that he was completely taken by surprise:

--
Holly KC9RP: “I was absolutely stunned! In fact, all I could say was me? I mean seriously, I was just absolutely floored.”
--

Holly, lives in Des Plaines Illinois has been licensed since 1965. He began his ham radio informational programming career in 1984 on a local Chicago Area repeater. This eventually lead him to become founder, moderator and guiding light of a weekly amateur radio audio feature magazine known as the RAIN Report.

--
Sample audio from Rain Report.
--

RAIN programming is distributed to hundreds of repeaters across the country via a telephone dial-up line, the rainreport.com website, by a subscription tape service and broadcast over W-A-Zero-R-C-R's weekly 160 meter informational net.

But that’s is only a small part of the Hap Holly story. Originally licensed in Escondido California at age 14, Holly who has been blind since age 7 served as a phone-patch station and net control for the famed WESTCARS traffic net until 1970. He then headed off to Principia College in Illinois and from 1970 to graduation in 1974, ran phone patches and kept radio schedules for many of

his fellow students.

Holly graduated Principia with a Bachelor of Arts degree in Sociology, and soon found himself in the Chicago area. There, he sought out world-class jazz accordionist Leon Sash, to pursue further training in music. As a professional keyboard player, Holly’s diverse repertoire of American music of the past six decades has made him a popular choice in the Chicago area.

Hap met his wife-to-be while he was teaching a class in non-visual perception to high school students at a summer camp in Buena Vista, Colorado. The two were married in August of 1976. Stephanie, who is sighted, received her ham ticket and KA9WKD callsign in 1986.

Over the years, Hap Holly has written articles for the Spec-Com Journal, Radio Scan Magazine and occasionally reports for us here on the Amateur Radio Newsline. Holly is also a common sight at the Dayton Hamvention, taping forums which are then incorporated throughout the year into his RAIN Reports. And since 1975 KC9RP has been an honored member of the Des Plaines Lions Club. He has also been a member of the Des Plaines Toastmasters since 1976. He and Stephanie are also active with Des Plaines Illinois Emergency Medical Alert system.

Named as this years Hamvention Technical Excellence award winner is Alan Waller, K3TKJ, of Laurel, Delaware. Waller was chosen for his work that lead to the interfacing the Internet to Amateur Radio.

First licensed in 1961, Waller combined his decades-long love for Amateur Radio and a burgeoning interest in the then-new Internet to design and manage the www.qsl.net and www.qth.net web sites. That was back in 1993. Since that time, Alan Waller's web sites have come to serve the needs of tens of thousands of ham radio operators worldwide by providing a vast technical reference platform, an electronic mail service, web page hosting services, and links to thousands of other ham radio related sites. And in the true spirit of the Amateur Radio, Waller's initial work utilized leading edge experimentation to see what could be done with the technology then available. This has developed into a mature, reliable service to the world wide ham radio community.

Rounding out this seasons winners are a pair of pair of space exploring hams who have been named as co-recipients of the 2002 Hamvention Special Achievement Award. Former astronauts Owen Garriott, W5LFL, and Tony England, W0ORE, are being honored for paving the way for manned ham radio operations from the space shuttles that has made ham radio a permanent part of mans exploration of space.

Owen Gariott, W5LFL was first. On November 28, 1983, Garriott, was launched into space aboard the space ship Columbia for the STS-9 mission. It was the Spacelab 1 mission and Garriott brought along the first Amateur Radio station on a crew-tended space vehicle. It was a simple Motorola hand held transceiver connected to a special antenna designed to fit in the Space Shuttle’s window.

Three days later, W5LFL came on the air and hams across the United States and around the world were witness to a historic radio transmission:

--
Owen Garriott W5LFL: “This is W5LFL in Columbia. W5LFL in Columbia orbiting the Earth at an altitude of 135 nautical miles passing over the U.S. West Coast and calling CQ.”
--

Among those who heard Owen Garriott's Amateur Radio transmissions from space was Lance Collister, WA1JXN of Frenchtown Montana. Collister, who is now W7GJ, is credited with being the first amateur to work an astronaut in orbit. Take a listen:

--
Lance Collister WA1JXN/W7GJ: “W5LFL on Columbia, WA1JXN, W-A-1-Japan - Xray-Norway, WA1JXN Frenchtown Montana standing by.”

Owen Garriott, W5LFL: “Hello W1JXN, WA1JXN, WA1-Juliet-Xray-November. This is W5LFL. You’re our first contact from orbit. WA1JXN, how do you read? Over?”
--

The success of Garriott’s mission lead to the development of SAREX -- The Shuttle Amateur Radio Experiment. And, over the years, SAREX permitted youngsters in classrooms around the world to speak directly with astronauts in space. But for this to happen, the technology of manned ham radio operations from space had to be enhanced. This aspect of the then new SAREX program fell to the next ham radio operator orbited: Tony England, W0ORE.

W0ORE flew into space on the shuttle Challenger in 1985. It was Mission 51F, Spscelab 2. In addition to the 2 meter FM voice gear, Tony England also had with him the first ever ham television station to go into space. Slow Scan yes, but capable of sending back high resolution images which hams on the ground equipped with SSTV gear could view live or record on a simple audio cassette for later viewing and historical archiving. From space, Tony England described the station he was using:

--
Tony England, W0ORE: “Essentially we’ve got a commercial TV camera that anyone could go out to their local radio store ant buy. We feed this into a scan converter built by a commercial outfit and modified by NASA Amateur Radio clubs and this takes a snapshot of the scene and digitizes it and put it in a memory.

Then its sent to a handie-talkie like this. From there we will send it over a wire up to the upper window upstairs and to this antenna when I get it up there in the window. Then it will be transmitted to the ground.

When we get going, we will be able to send color TV images of what we are doing on board as a series of snapshots updated every 10 or 20 seconds. Amateurs anywhere on the ground will be able to receive them, and ones with scan converters will see the pictures.”
--

That flight also marked another first. The first ever two way television -- ham radio television -- to and from space.

Tony England went on to flight prove both the improved FM voice and then new SSTV systems. The SSTV was so successful that NASA gave very serious consideration to a permanent installation on all shuttles for back up communications. More important, the early on-orbit operations by Own Garriott W5LFL and Tony England W0ORE made possible the thousands of educational contacts between children in school classrooms and the crews flying in space. First, on board the shuttles, and now as a permanent part of the International Space Station.

Hap Holly KC9RP, Alan Waller K3TKJ, Owen Garriott W5LFL and Tony England W0ORE will receive their honors at the Hamvention Awards Banquet slated for Saturday evening, May 18th at the Nutter Center in Dayton Ohio. Amateur Radio Newsline will be there to bring you this story and all the news about Hamvention 2002. (ARNewsline™ from Dayton Hamvention® news release. Some audio from "Amateur Radio's Newest Frontier" and "SAREX - The Shuttle Amateur Radio Experiment" video presentations)

RADIO RULES: FCC RESUMES VANITY PROCESSING

Vanity license processing is getting back on tract. According to a Legaue bulletin the FCC now has all outstanding vanity applications filed last October in hand and is ready to resume routine vanity processing. Until recently a single missing vanity application had been holding up a backlog of more than 2000 vanity applications. The FCC credits the ARRL in part with helping to locate applicants and resolving the problem. (ARRL, FCC)

RESCUE RADIO: AMATEUR RADIO EMERGENCY COMMS SUMMIT

The first ever Amateur Radio Emergency Communications summit was held in Indianapolis last week. Amateur News Weekly's Jack Parker, W8ISH, reports on the success of this first meeting.

--
They came from the Red Cross, Salvation Army, ARES, RACES and even CB-radio's REACT team. Two dozen representatives of different Amateur Radio emergency communications groups met in a Federal Building training room to find ways of helping local and state emergency management organizations. The summit was organized by Marion County ARES director Mike Palmer, N9FEB. Palmer cited a need to develop better communications and cooperation between the different groups.

Many amateurs wear two or three different hats when it comes to providing public service. Palmer wants to identify those who are willing to help and to better utilize the voice and data communications available in the Marion County Amateur Radio Community. Many of the summit participants agreed this type of effort is long overdue.

Members of Army-Navy and Air Force Mars, as well as the Indiana Wing of the Civil Air Patrol offered their services during times of disaster. Everyone agreed this was a good start and look forward to future efforts to better train and organize Amateur Radio Emergency Communications in Marion County and Central Indiana.

Reporting from Indianapolis for Amateur News Weekly, this is Jack Parker W8ISH.

--

According to Jack, everyone came away from the meeting knowing that cooperation between groups is a key element in providing better service to the public. (ANW)

**

RADIO RULES: FCC ADOPTS AMBER EAS EVENT CODE FOR CHILD ABDUCTION CASES
The Federal Communications Commission has announced the adoption of a Report and Order amending the Emergency Alert System rules. Included are several new EAS event and location codes, which broadcast stations and cable systems may use to alert the public in the event of state and local emergencies. Of these, a new Child Abduction Emergency event code may be the most interesting to hams involved in Search and Rescue and who have E-A-S decoders installed in their repeaters.

The plan is described as a voluntary partnership between law enforcement agencies and the media that will be used to alert the public of serious child abduction cases where police believe that the child is in danger of bodily harm or death. Under the plan, radio and television stations will be permitted but not required to interrupt programming to disseminate information concerning serious child abductions when the new Child Abduction Emergency code is received. It could also be used by hams as an automated call to action to help find a missing child if used to activate an E-A-S equipped Amateur Service repeater.

Police departments say that every minute counts in dealing with an abducted child situation. In adding the Child Abduction Emergency code the FCC says that its responding to public concerns. (FCC)

**

ENFORCEMENT: FCC COMPLETES GEORGIA ARRL VEC EXAM SESSION AUDIT

The FCC has wrapped up an investigation into apparent irregularities at five ARRL VEC-sponsored Amateur Radio examination sessions in Georgia during 2000 and 2001. As a result of the probe, FCC Special Counsel Riley Hollingsworth says that several examinees will be called back for partial retesting:

--
Riley Hollingsworth: “We determined reviewing all of the information that was brought to our by the League that eight examinees will have to be retested on the code element. The ARRL has also relieved ten VE’s of their duties as volunteer examiners.”
--

According to the ARRL Letter, all V-E’s who might have been involved were suspended after the FCC investigation began last year. (FCC, RAIN)

**

ENFORCEMENT: A REPEATER OUTSIDE OF THE BAND

The FCC is also looking at the operation of repeater in the Metro New York City area. Again, the FCC’s Riley Hollingsworth:

--
Riley Hollingsworth: “We opened an inquiry into allegations that an uncoordinated repeater operated by Thomas Batista, KC2DDD, and Gerardo Arias, N2IFU, in Corona and Staten Island New York. Now that repeater is not only causing interference to a coordinted repeater, but the input is apparently on a frequency not even allocated to the Amateur band. So, needless to say we are real interested in reviewing that response when it comes in.
--

What Hollingsworth will be looking for is an answer to why the machine is using 143.020 MHz as an input frequency as well as why its on the air without coordination. 143.020 MHz is a full 800 Kilohertz below the bottom edge of the 2 meter Amateur band. (FCC, RAIN)

**

CONVENTIONS: SOUTH EAST VHF SOCIETY CONFERENCE

On a far lighter note, the Sixth Annual Southeastern VHF Society Conference will take place April 26th through the 27th in Oak Ridge, Tennessee. And they too are putting out a call for papers. If you are interested in participating, please contact KG4QDZ by e-mail to kg4qdz@arrl.net. (VHF Reflector)

**

CONVENTIONS: CHARLESTON HAMFEST MARCH 16

And the 18th Annual Charleston Area Hamfest and Computer Show will be held Saturday, March 16, 2002 from 9 AM to 3 PM at the Coonskin Armory in Charleston, West Virginia. Talk-in is on the 145.35 MHz repeater. Admission is $5 and there will be free parking. More information is available by e-mail to n8tmw@arrl.net. (N8TMW)

HAM RADIO POLITICS: NCI LEADER CALLS FOR ELECTIONS

Bruce Perens, K6BP, the founder and an incumbent director of No Code International says that its time for new directions for the group and has called for elections. Amateur Radio Newsline’s Norm Seeley, KI7UP, has more:

--
According to Bruce Perins, K6BP, when he started NCI in 1997, he never dreamed that it’s goals would be achieved so quickly. But says Perins; “we are most of the way there.”

Perins notes that last year the International Amateur Radio Union voted to ask for the removal of the international treaty provision requiring Morse Code testing for Radio Amateurs. Now Perins observes that even ARRL has voted in favor of removing code requirements from the international Radio Regulations.

With what he terms as -- no remaining credible opposition to NCI's cause left on the international level -- Perins says that it is time to turn NCI’s focus to domestic policy. He says that for NCI to take an appropriate role in the end-game of the no-code battle means cooperation with national societies like the American Radio Relay League. And to do this, Perrins believes may take some new people.

So Perins has asked that an election for new directors be held no later than April 30th of this year. He also says that any person who was an NCI member on December 31, 2001 can be a candidate for director, and is eligible to vote in the election.

For the Amateur Radio Newsline, I’m Norm Seeley, KI7UP.

--

More information about No Code International is on the web at www.nocode.org. (ARNewsline with information from K6BP)

WRTC-2002: ORGANIZING COMMITTEE ANNOUNCES THE COMPLETE LIST OF OFFICIAL ON-SITE REFEREES

The WRTC 2002 Organizing Committee has named a full list of on-site referees for the upcoming games. The committee says that it received more than 100 highly qualified applications and those chosen were from that group. A full list of referees and other information is available on the web at www.wrtc2002.org (WRTC2002)

**

DX

In D-X, word that Dave Cree, G3TBK, has returned to work in the Caribbean. Throughout March Dave will be active as J88DR from St. Vincent. For the first two weeks of April look for him J3 slash G3TBK from Grenada. Operations will be on all bands, but concentrating on the WARC bands, mostly on C-W, but with some SSB. QSL to Dave's home call either direct or via the RSGB bureau. (RSGB)

The New Zealand Amateur Transmitters Society is warning hams world wide of what they say is a pirate operation. According the NZART News, a maritime mobile station using the callsign ZL2TO and the name Tony has been heard recently operating on nets on 15 Meters. This station currently gives his location as the Cape Verde Islands. Only one problem. The ZL2TO call sign is allocated the Waitara Amateur Radio Club. (NZART)

And the South Africa Radio League news service says that anyone who has held a QSO's with 7Q8 slash ZS6GH or C9 slash ZS6GH should write them off . SARL says that these have been declared null and void because license or authorization to operate was issued by the telecommunications regulators in Malawi or Mozambique. (SARL)

**

THAT FINAL ITEM: NOMINATIONS SOUGHT FOR THE YOUNG HAM OF THE YEAR AWARD

And finally, we started this weeks newscast with a story about awards. Lets end it on a similar note as we here a Amateur Radio Newsline officially open the 2002 nominating season for our own Young Ham of the Year Award.

The Young Ham of the Year award was created in 1986 by amateur Radio Newsline producer Bill Pasternak, WA6ITF, to fill what he viewed as a void where younger members of ham radio society were often overlooked:

--
Bill Pasternak, WA6ITF: “When I was a young ham in the 50’s and 60’s the good deeds of young hams were often overlooked and ignored. When I grew up I was fortunate enough to be in a position to remedy this and thats how the Young Ham of the Year Award program came about. Thats how it came into being”
--

The award as originally envisioned as very low budget. One idea was for a certificate that would be mailed to a ham, age 18 or younger who had shown some exceptional ability or performed some heroic deed that set him or her apart from the crowd. When Bill mentioned the idea to Chip Margelli K7JA, of Vertex Standard back in the company’s days as Yaesu USA, the idea quickly expanded. Margelli offered company support on the spot:

--
Chip Margelli, K7JA: “When Bill Pasternak gave me a call and dsescribed the project to me in the tiniest bit of detail it was obvious that this was a no-brainer and something that we as a company at Yaesu wanted to encourage. So, I jumped at the opportunity to be a major contributor and it has been a great project ever since.”
--

The award now had substance, but it lacked a permanent home. One was found in 1993 when it was invited to the Huntsville Hamfest:

--
Bill Pasternak, WA6ITF: “The way we got to Huntsville? Simple. We advertised. We put a notice into the newscast that we were searching for a permanent home. The answer came in a note from Scotty Neustadter, now W4WW, who is the Huntsville Hamfest Chairman. Scotty basically said bring it to Huntsville. And we did.”
--

While the presentation ceremony did go to Seaside Oregon in 1994, it returned to Huntsville in 1995 where it has been ever since. And in 1996 a second major corporate underwriter came on board. C-Q Magazine. Rich Moseson W2VU, is editor:

--
Rich Moseson, W2VU: “We at CQ have always thought that it is very important to promote Amateur Radio to young people and we saw that co-sponsorship of the award was the way to help do that.
--

What CQ did was to add to the Young Ham of the Year awards chest something very special. A week of fun and excitement at Spacecamp. Today, with corporate sponsorship from Vertex-Standard USA and CQ Magazine, and support from countless others including the ARRL, Dave Bell Associates and Rosewood Communications the Young Ham of the Year Award continues to honor the Amateur Radio related achievements of those hams age 18 or younger. And now its time to find a fitting recipient for 2002.

Full details, rules and a nominating form are available right now on our website at www.arnewsline.org. Just scroll down to the Young Ham of the Year Award area and click to download. Or you can send a self addressed stamped envelope to the 2002 Newsline Young Ham of the Year Award, 28197 Robin Avenue, Santa Clarita California 91350 and we will mail back the materials.

The Amateur Radio Newsline Young Ham of the Year Award is a one of a kind. It honors the youth of ham radio and in doing so, we hope it helps to insure a bright future for the hobby and the radio service that all of us love. (ARNewsline™)

I would check the finger stock first. The coil should not be able to move
around in the finger stock. It should be a snug fit. Be sure the copper
coil is clean. use some very fine sandpaper and make it shine again. Check
with an ohm meter while running the coil up and down. (NOT TRANSMITTING).
One lead on the body of the antenna and the other lead attached to the whip.
I think this will solve the problem!

I'm just guessing it's Rohn 20. I heard that it was smaller than 25
and my foot (size 8-1/2) barely fits between the poles. The previous
owner says he's had it for 30 years, and he got it second-hand. It
has that zig-zag pattern of cross supports like Rohn 25.

I've decided against the beam, instead hoisting a G5RV from it and
probably mounting a 2-meter J-pole on the top. I may even install an
FM broadcast dipole on it for the garage stereo. The tower, installed
next to and supported by the garage, should be able to handle that.

Took the rotor off this evening. Underneath is marked ATR-4, or
something-4. I can't remember the prefix exactly.

ACE Hardware will be my first stop on the way to work tomorrow morning
for replacement hardware.

Thank you for your kind help. You and the other responders contribute
to the fraternity of ham radio.

4927. Learn NVIS

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-11 05:00:50 UTC
From: DJ <kb5ylg@attglobal.net>
Message-ID: <3c8c3d31_3@news1.prserv.net>
Source record: 146915
Cross-posted to: alt.ham-radio.hf,rec.radio.amateur.antenna

This weekend I participated in a multi-state MARS emergency communications simulation and test with a scenario of a Terrorist Attack with multiple attack modes and multiple cities in harms way. Good practice.

During the test I learned something pretty important that you might benefit from, too.

During one of the Texas nets, there were multiple observations about how bad the propogation was
really poor on 40 meters (around noon today).

However, after the net closed, a net from another state came on and all their signals were coming in perfectly clear and readable.

What was the difference? Proximity. What effect could account for hearing stations further away easier than hearing stations nearby? The dead or skip zone!!

The Texas stations were not close enough to each other to work the ground wave propogation. But they were not far enough apart for skywave propogation to work well for them either.

The solution? NVIS.

Near Vertical Incidence Skywave operations. Sounds technical, but it's easy.

Most amateur radio antennas are designed and positioned to radiate their signals as far to the horizon as possible, to extend the distance of the skywave propogation. That's the "low angle of radiation" desired in antennas, meaning more energy is radiated out to the horizon. The result can leave a dead zone between the end of the groundwave region, and the beginning of the skywave returning to earth.

To improve signals into the dead zone, you have to chance the incident angle from nearly horizontal to more vertical.

The easiest way to do this?

Lower your antenna. That's it.

As it turns out, the closer an antenna is to the ground, the more of it's energy is directed up (nearly vertical), instead of out. I have read several articles about Near Vertical Incident Signal operations, but now I know why it is so important.

Not all communication is directed to the other side of the planet.
Sometimes we want to talk to people just 100 miles away, for example.

What height should the antenna be for NVIS?

According to a study done by the military, about .15 wavelength off the ground is the best mix of suppressing ground noise, and getting good near vertical radiation.

For 40 meters, that's about 20 feet, give or take a few feet. Works fine for dipole or vee configuration.

I added a 40M and 80M dipole to my tower today, at about 25 feet, and got instant good signal reports from stations that earlier could hardly make out my signal.

What if I want to talk to stations that are both near (in the NVIS zone) and far (Skywave zone) during the nets?

Well you can try to find the best height for your antenna that will give you propogation to the areas you want to work. Or just use two antennas and switch between them using an antenna switch. Any station complaining they can't hear you may hear you quite well if you switch to your alternative antenna position.

This NVIS mode is also good for getting signals over mountains or other obstructions, too.

It's what he says it is. You lose efficiency by having the elements
closer together than 90 degrees due to cancellation. It's not quite as
good as having all the dipoles spread apart. It should be quite usable
though. MK

Hello,

I have been looking on the net for a schematic for building a 5/8 wave vertical antenna! I did find some schematics but unfortunately never with a good calculation or explanation how to make the coil.

Who can help, or is having a good idea how to make one?

I want to make it in first instance for 2 meters.

Thanks in advance,

Michel

Source record: 146821

Download in a few seconds program BOTLOAD from website below. Very easy to use.

Will tell you bottom loading coil inductance for any height of vertical antenna at any frequency.

Will also tell you how many turns to wind on the coil for any given length and diameter of coil former.

For a 5/8-wave and similar verticals there is no point in locating the loading coil anywhere except at the bottom.

Choose the exact height to make the feedpoint exactly 50 ohms. Or 75 ohms if you prefer.

Download BOTLOAD now.

4934. Re: References on Half wave end fed top loaded vertical ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-11 13:46:34 UTC
From: jim.bolinger@lintek.aeroflex.com
Message-ID: <8d5ec8a2.0203110546.6f6cf8a2@posting.google.com>
Source record: 146822

I doubt it, since it is the current issue.

The authors may have something on the web somewhere. I will look.

The basic design looks similar to a coaxial sleeve dipole or a
4-radial ground plane with the radials hanging straight down. What is
unique about it is how it is fed. Unfortunately their description is
a little vague as to the details. The 'sleeve' part is actually 4
wires around the center mast, essentially forming four 1/4 wave open
stubs spaced 90 degrees around the mast. This attaches to the center
of the half-wave tall mast, which is grounded at the bottom. The feed
point is on the 1/4 wave stubs a short distance down from the attach
point. Exactly how the feeding is done is unclear.

Something like this, turned upright. F is the feed point. (Don't ask
me... I don't know how it works either!)

```
g
r
o ------------F---
u |
n--------------------------------------
d |
------------F---
```

They claim that they designed it using some MiniNEC variant, but don't
give enough details for you to try it yourself. I haven't had a
chance to try figuring it out yet.

Hi,

I have just modeled the CobWebb antenna for 10-15-20 on EZNEC and I must be wrong or it has quite a good gain in the three bands, problem is very limited bandwidth.

Could the reduced bandwidth be due to very low feedpoint impedance (~ 5ohms)? If so, how could this be improved? Maybe by placing the different halos at different heights to reduce mutual coupling?

I include the model file in a post to follow this one.

Toni

Corey,
The 4" extension may be making the antenna too long
for the higher bands (using the very top portion of the
coil). I'd try removing it and seeing what happens...

What I did was take 3/4 wavelenth of copper tubing, wind 1/8 wavelength
into a coil at the bottom, solder to the center of an so239, with 4 1/4
wavelength groundplannes. Flimsy as heck, but worked like a charm.
(you may wish to build it into PVC conduit)

4940. VLF/LORAN C antenna?

There aren't any.

Loran C antennas consist of an 8 foot whip and either a matching coil or
a 100 KHz resonant LC circuit, usually with a built in pre-amp.

40 meters was tore up. We were having solar flares, etc. The band is
usually not as bad as it was yesterday. MK

4944. WANTED: how to homebrew a better SWR noise bridge

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-11 15:49:44 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0203110749.7c597dd0@posting.google.com>
Source record: 146832
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna

I have an MFJ-212 Matchmaker, a noise bridge device I use to adjust my tuner or antenna for minimum SWR. I turn on the Matchmaker, and I can listen to the noise on my transceiver. To minimize the transmiter SWR, I adjust my tuner or antenna for the minimum noise level (as heard from the speaker or as seen on the S meter).

Can anyone here explain how such a noise bridge device works? I have seen a few circuit diagrams, but I would like to know what various parts of the circuit do. (I know there is a small, low-powered transmitter that sends out a fraction of a watt at a wide range of frequencies. The forward voltage and reflected voltage have to be measured. Etc.)

I have just thought up a project: a better SWR noise bridge. I do have a few gripes about this device, and this is my inspiration to build something better. (This project will also give me much-needed practical experience with RF circuits.)

First, I'd rather NOT rely on listening to the transceiver speaker, as signal spikes (whether from noise spikes or other hams transmitting) make it challenging to tune for minimum noise from the noise bridge. I want my homebrewed SWR noise bridge to have its own speaker, which I guess would be less sensitive and would be driven by the SWR ratio and NOT connected to the antenna or transmission line. An alternative is to use a series of light bars/LEDs, analog meters, or a digital display to show the SWR.

Second, I'd like my homebrewed SWR meter to allow for both coarse and fine tuning. The MFJ-212 Matchmaker is very crude - I cannot distinguish between an SWR of 10 and an SWR of 100. Even an SWR of 5 doesn't sound that different from an SWR of 100. Since bandwidth can be VERY narrow on the lower bands (like 40m and 80m), this crudeness is frustrating. I would like my homebrewed SWR noise bridge to have several different modes, such as a crude mode to be used for SWRs over 100 (so I can tell I'm tuning in the right direction on 80m), a coarse mode to be used for SWRs under 100, a medium mode for SWRs under 10, a fine mode for SWRs under 5, and a super-fine mode for SWRs under 2.

The MFJ-212 Matchmaker has some characteristics that I do like and would like to duplicate, however. One is its ability to easily handle at least 100 W (supposedly, as I'm not in the habit of testing this) if you accidentally transmit. Second is the ability to bypass the noise bridge circuit by turning the device off (as I would rather not test its ability to handle 100 W). Third is the use of a 9V battery (which gives me a way to use up partly-used smoke detector batteries).

What does it take to homebrew circuits for VHF, UHF, and microwave frequencies? From what I understand, the higher the frequency, the greater the impact of stray capacitances and inductances as the wavelength contracts to the point that it is no longer much larger than the electronic components. I guess this is part of the reason why there are fewer SWR meters and antenna analyzers commercially available for VHF-and-up as compared to HF.

What does it take to overcome the impact of stray capacitances and inductances? More careful construction? Stripline? Anything else?

Monte:
A couple of comments:
I'm not sure what tower that is, as to my knowledge, Rohn never made a tower with the zig zag bracing smaller than 25. 20 and 20G (20 was painted, 20G galvanized) was about the same face size (12.5" outside, 11.25" on centers), but the leg tubing was smaller in diameter, and it only had horizontal "W" cross section straps around it. I am going to dig out my archival Rohn file if I can still find it and double check, but I'm wondering if that is the top portion of one of their self supporting towers. I just thought of another possibility. There was a small government tower which came through MARS back in the 60s or 70s. The zig zag was welded on the outside of the legs, instead of between them as the Rohn is. And the sections went together with some sort of half turn clamping mechanism. Was your source possibly a MARS member back then?

The hardware should be at least grade 5 and it is highly desirable that it be galvanized. Having said that, the only source of same which I am sure of is Texas Towers, where I but new bolts for my 25G. I did discover a source of galvanized grade 8 bolts out in California last month, but they only sell in box (100) quantities.

Twit.

What's the difference between skywave and Skywave? See the cloud burners section of W4RNL's web site if you really want to try to understand what is going on. If the ionosphere doesn't cooperate, it doesn't matter what you call it, it won't propagate signals from point A to point B. I was working what you now call NVIS back in the 50s on 75 and 40 meters. Should I have gotten permission first?

I would suggest purchasing a used reciever on e-bay or the like. You can
get a much better reciever in that price range in the used catagory.

Also, I would check into the reviews at eham.net

example:

Hi

With coax that is constructed with center conductor, a foil inner shield, followed by a braid outer shield, should the inner foil shield be grounded as well as the outer shield or should it be allowed to float.

If using a match xfmr with this type of coax, would you connect one side of the xfrm between antenna and a grounded inner foil and the other side of the xfmr between the coax center conductor and the outer (ungrounded shield).

I would appreciate any other schemes that anyone could suggest.

I take your description to be a 2 wire top hat on a verticle. Or a T shaped antenna.
I am attempting to do the same thing.

On frequencies where the wire is a multiple of a half wavelength, the impeadence will be high and minimal grounding is required. On frequencies where it is an odd multiple of a 1/4 wave, it will be a low impeadence and 4 resonant radials, at least 2 feet above the ground, or 60 burried radials would give good performance.

Check out Verticals with out Vertigo by w4rnl. his web site is Cebik.com

I think you already list the significant attributes; but in a nutshell
it is a white noise generator (white noise meaning a broadband
emission of RF - from ELF to low VHF).

Being better means one of two things: more power, or better white
noise characteristic. It is highly unlikely you need a better white
noise characteristic (if the bridge works at any frequency, it works
just at well at all frequencies).

>
>First, I'd rather NOT rely on listening to the transceiver speaker, as

Hi Jason,

Nearly all that you ask for above is a product or problem of your rig. The noise bridge approach is the simplest, (arguably) cheapest alternative to on-air tune up. An even simpler and (unarguably) cheaper method would be to use on the air signals. The problem here, solved by the white noise source, is there may be no signal, the signal may be variable for many reasons, the signal may drift and so on. The white noise source on the other hand provides a fixed level signal at ALL frequencies that is usually greater than over the air signal levels.

However, as to this last, in a 3.2 kHz band with at ANY particular frequency we are talking about a total noise (frequency) power of -73 dBm for an S-9 reading (if, in fact, you experience it at this level). This is a far cry from a fraction of a watt nearly 100 dB away; and this disparity reveals how the power is divvied up along the RF spectrum.

If you want to improve your bridge, it would be to bump up the gain to 1W or add a wideband 10dB gain amplifier. As simple as this point may seem, it will definitely test your self-challenge:
>(This project will also give me much-needed
>practical experience with RF circuits.)
Building stable wide band amplifiers is the bed rock of RF design. You should have a copy (or good treatment) of H.W. Bode by now(?).

It could also serve as the basis for many simple Shack radio standards. My white noise source consists of a weakly, LED illuminated, Photomultiplier Tube terminated with a 50 Ohm resistor (the apparent source as the PMT is a constant current device). This provides me with a white noise bandwidth out to >1GHz.

Hi Jason,
My experience has been that using 'dead bug' construction (also known as 'dirty') works very well up to 1.5GHz and perhaps higher. Lead length must be reduced to a minimum (zero if possible) and this type of construction allows for this quite well.

Hi Jason,

Modularize your stages or functional blocks: mixer on one board, VCO
on another board, MOD/DEMOD on yet another and so on. Shield each
module (should go without saying). By pass power and control lines.
Observe proper grounding techniques.

Actually, the last point about observing proper grounding is the most
difficult to implement. The failures to observe are found in ALL the
common design problems (coupling problems, birdies, instability,
offset, noise...). Modularization tends to increase this hazard, but
mono designs do not fare much the better.

You also need to characterize each module. Build and test it to
complete specification. It is highly likely you want to preserve your
investment; then make it generally useful. For example, design the
mixer board to a spec that is more easily met across a spread of
applications you might want to test it in. This means that most I/O
will be designed around the 50 Ohm standard. You will already find
that most commercial packages anticipate this.

What you already describe as difficulties can be limited to the module
board and the problem isolated to an obvious source. Most UHF/SHF
design is quite intuitive and straightforward when you consider the
geometries and wavelength. On the other hand, there are greater
difficulties that arise from the complexity of the modulation, or in
the control of AGC (or its application). That is to say, there is

usually more grief to be found in the "system" signals than in the RF path.

But I don't think you'd want that kind for an antenna. I prefer the
plain wire variety. The most common is 17ga or 14ga galvanized
steel wire. Another fairly common is some guage of aluminum wire.

Sure, you can get the fiberglass cord or tape (especially the tape
for horse enclosures since it is very visible) but...

A half-square is a pretty decent antenna. However would there be any improvement with using 1/2 wave length verticals vs 1/4wl on 20m and above? Maybe the answeer is NO since folks would be doing it already but curious why not.

Hello folks,

This evening I wound the main cable of a MW receiver around a ferrite rod,
but that made no difference. I did however do some more tests with
different radios. Yupiteru MVT7100 received the signal all over the MW band
where there were no stations but the receievd signal was weak. Sangean
ATS909 received the signal only slightly. It was extremely weak indeed.

Funny....The Cessna 172 I fly has a Loran receiver in it, and I don't
recall seeing a 8 foot whip anywhere.

What would be wrong with a multiturn loop? A foot or two in diameter,
resonated with a capacitor?

For fixed operation it should work fine. If you are mobile you would
want a whip.

My guess would be that they are talking about the total power being emitted, which would be dBm, regardless of the type of signal.

The same thing as saying that hams can't use more than x kW (depending on band), whether their bandwidth is 100Hz (cw), 3 kHz (SSB), 6 kHz (AM), 15 kHz (FM), etc. It all must add up to less than x kW.

OK, I can see that a white noise generator wouldn't work here. I
guess some type of miniature signal generator (with a knob or other
control on the device) is needed to ensure transmission at just one
frequency.

The white noise signal isn't always much greater than over-the-air signals. The over-the-air signals can be significant on 40m and 80m at night. And while my radio does have an attenuator, this affects the white noise AND the on-air noise.

That is because Brother Blair is used to marine installations. There is no such thing as a "resonant" antenna for Loran. All you do is stick a **vertical** whip into the air as long as you think reasonable. For marine, this may indeed be 8'. For aviation, it is generally 24" or less. Mine is 18" of brass brazing rod epoxied into a BNC connector.

Don't put it out into the wingtips. I tried this design on the prototype Long-EZ and it went stark nutz every time Dick rolled it.

>
> What would be wrong with a multiturn loop? A foot or two in diameter,

Go through the calculation for a 100 kHz. loop of any reasonable diameter and how many turns and how much capacitance. It is an interesting number.

>
> For fixed operation it should work fine. If you are mobile you would
> want a whip.

That's true. 18" works all the way from out in the Pacific to roughly Scottsbluff Nebraska for me. I really don't have the huevos to find out single-engine how far out into the Pacific it would work {;-)

For the first questions, have a look at some of the very good postings
that have been made on how directional couplers work. You should be
able to find some in the Google archives. For example, I posted one
explanation back in 1992 under the title, "A (long) look at SWR &
directional pwr mtrs" that you should be able to find. But there are
plenty more of them...some other by me, many by others.

One thing to consider in building your dream tuner-tuning aid is that
noise excitation is very broadband, and you ultimately need a circuit
that's more narrowband than the tuning you're trying to achieve. Your
receiver does this for you with a noise bridge: you only listen to a
small piece of the spectrum. If you're going to have a speaker in
the tuning aid, you might consider using narrowband excitation instead
of narrowband detection.

There've been some articles on using the very sensitive Analog Devices
logarithmic RF detectors to measure SWR. You should probably have a
look for/at them. Some of them probably come very close to what you
want. Actually, one of your complaints is that it's hard to tell that
you're getting closer to proper tuning when you're a badly de-tuned.
You could help that a LOT if you displayed not SWR but load impedance.
There's a lot more info about how to tune if you know the line is
presenting 2 ohms, or 5+j61 ohms, or 1250 ohms...all about 25:1 SWR
(to a 50 ohm system).

Cheers,
Tom

I seee some problems with this. 1st, you could not feed it at a corner, as this would now be a voltage loop. 2nd, the horizontal section would now be an in phase 1/2 wave and would radiate- this is not the case for 1/4 wave legs (where the 1/2 wave section is self cancelling)..

You need the element or the insulators? I gave up on Hy Gain's cheap fiberglass and fabricated an element mount from a piece of 2" X 4" fiberglass I beam about 3 feet long. U bolt a small plate to the boom to hold the middle of the I-beam, and u-bolt the elements to the web of the I beam.

Which makes me wonder what kind of antenna you were using
before. It wasn't a multi-band vertical, was it? If it
was, your improved results with the dipole, while valid,
could also be partially due to better overall radiation
efficiency.

Your experiences do mirror a very large volume of amateur
radio observations and operating experience on 80 and 40
meters accumulated over the past seven or eight decades.
Not Really Important Stuff like MARS, but it does give one
a feel for how the ionosphere boils and bubbles.

A 1/2 wave still needs radials to reduce ground losses, if ground
mounted. It just doesn't require them to be a "complete" antenna. It
is much less lossy than a 1/4 wave though if both are on the ground.
You will notice all BC stations that run 1/2 waves still use a set of
1/2 wave radials. The 60 buried radials would give good performance,
but the 4 radials 2 feet above ground would not be near as good.
Ground losses will be fairly high. You really need to be a 1/4 wave
up, or near it, to have good performance from 4 resonant radials
elevated. Even at an 1/8 wave up 4 radials is only marginal. This is
why Cecils 40m ground plane never beats his dipole. :(It's too low
for the amount of radials used. "Unless he's changed it since I last
heard about it" I ran a 40m ground plane with 4 radials at 1/4 wave up
and it never lost to the dipole at any distance over 1000 miles. But
thats about as low as I can go and get decent results with only 4
radials. At that height, I would need about 10 radials to equal the
"BC standard" of 120 radials or more. As it was my 4 at 1/4 wave up
equaled about 60 on the ground. 4 radials at two feet up, are not much
better than 4 on the ground. The only real purpose in raising them off
the ground is to keep from detuning them so they will be resonant. MK

You would probably be better off with a well designed 1/4 wave ground
plane on 2m than a 5/8 gp. The "usual" type of 5/8 gp is a bad design
for low angle 2m use. You would want to make a "dual 5/8" collinear if
you want to see any real improvement. I have given the formulas for
5/8's many times and should be in deja news. Rather than retype it all
here, I'm going to give you a program which will calculate a 5/8 GP
for any freq, and also includes the formulas in the program. This
program also will do simple dipoles, etc, and also will do tuned
stubs, quarter sections, etc. It's fairly handy. Reg's program will
work also, but this one has a section made just for 5/8's. Look under
"advanced antennas" in the program. I put the program on my server.
Don't worry, there is no viruses and it's pretty small... It's at :
http://web.wt.net/~nm5k/hdqtenna.exe
The program is DOS, and will run in a windows DOS box no problem. It
was made by N5HDQ up in northern Texas.
For examples of why I don't like the "average" 5/8 on 2m, check:
http://web.wt.net/~nm5k/acompari.htm

Bob and Richard's advice is spot on. Solder components directly to bare copper board and minimize their lead lengths. Modularize everything (SMA jacks and the Hammond 1590-series boxes are your friends). And watch out for ground loops (I would not put a VCO in its own chassis, because you will NEVER get the ground currents out of the tuning line).

Ugly construction is usable to 2 GHz easily. If you keep your connections under 1/10 wavelength or so (~1 cm at 2.4 GHz), then you can avoid a lot of the nasty transmission-line behavior that people usually worry about at these frequencies. Just rely on 50-ohm building blocks as much as you can (if Hammond is your friend, then http://www.minicircuits.com is your next-door-neighbor who works for Victoria's Secret), and plan to give up about 0.5 dB per device due to VSWR.

There are a few photos of hand-wired VHF-to-microwave projects on my site (below), including a complete synthesizer with 1 Hz resolution between 1 and 2 GHz that fits in a single 4x2x1 Hammond box. The ugly RF wiring is completely buried under other parts, but it's there.

I added 4 radials for a total of 8 and it still usually loses
to my 75m dipole up at 40ft. A ham in Iowa checked into the
Good Old Boy's II Net on Sunday night. I quickly switched over
to the vertical to see the difference. He was S9 on the dipole
and S7 on the vertical.

I was listening to 75m the other night when I pulled into the grocery store parking lot. My screwdriver was set on 40m and I made a mental note to tune it to 75m when I finished grocery shopping. I came back to my pickup, put my groceries in the right hand part of the cab and started walking around the rear of the truck to get in on the driver's side. My screwdriver was busily tuning itself toward the 75m setting as if by magic. I got a weird feeling as I unlocked the driver's side door and looked to see what was going on. I had put a five liter box of wine down on the screwdriver control box.

Chapter 2 of the Antenna Book, edition 17 and previous, has a graph of capacitances of spheres, discs and cylinders as a function of length (with diameter equal to length). This is from a Sept. 1923 (!) QST article on end-fed half waves. It is included in the QST CD series which somebody may be willing to copy for you. Be happy to, but my printer is going to be out of order until I can get around to getting a new ink cylinder, which may be longer than you want to wait. I'll let you know when. 73, Hal, W8UYA

4984. Re: Double shield Coax connection

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-12 03:37:22 UTC
From: "Bob M." <xxxxx@yyyy.zzz>

Source record: 146771

On some foil + braid coax, the foil is permanently bonded to the center insulator and is a real pain to remove. On others, it's wrapped loosely and can be simply snipped off and unrolled. In either case, it _IS_ part of the outer shield. If it's bonded, it should go INSIDE of a connector's shield connection; if it's just wrapped around, you can cut it off and put just the braid on the OUTSIDE of the shield connection. Naturally, this depends on the type of connector being used. For example a mini-UHF crimp connector expects the braid and some outside insulation to go outside the outer shield, then a ferrule goes outside everything and crimps down. If the foil is bonded, it can go inside the outer shield, leaving the braid and outside insulation to be under the ferrule. If you're using an ordinary UHF connector, the braid and foil can remain together and will end up inside the connector. All you can really solder is the braid anyway without melting the center insulation.

Hope this helps.
Bob M.

If you need just a bit higher performance than some of the minicircuits
stuff, you might want to try www.stanfordmicro.com. They even oem
some of the minicircuits stuff. Richardson in the US distributes their
stuff, and it is readily available.

One part of note provides about 1.6dB NF, and has better than 10mw output
power. It is also SiGe which will do better in some cases (e.g. LF noise)
than more aggresive PHEMTs.

There is a designers kit for Stanford micro stuff, that also includes some fabricated PC boards to build example circuits.

John

Jim, thanks. A bandwidth for the measurement is required for it to be meaningful and in the ham case it may be 3kHz -- I'm not sure. My signal has a bandwidth of over 1GHz. The problem is that I can't find out for sure what the measurement bandwidth is in this FCC spec. I'm sure they know it and probably a lot of other folks know it who regularly deal with the FCC --but I not sure of it at all (I think it is 1MHz minimum).

Emery cloth could be also be used for cleaning up the copper. I also use an eraser or pencil eraser to assist, somewhat labor intensive, but make sure you clean up the residue. Tuner spray w/air works well. Good luck.

You're question is too broad. VHF is considered to start at 30MHz, right next door to HF. It's an arbitrary division. If you are working at 35MHz, or even 50MHz, construction will be almost identical to construction in the HF range. Of course, you can be sloppier at 3MHz than at 30MHz, and as you move upward in frequency, you have to be more careful. At 144MHz, you have to be more careful, but there is no real difference in construction techniques. It's only when you get up into UHF and more so microwave, do you start using radically different construction techniques.

I think over the years, the definition of difficult construction territory has move up in frequency. Forty years ago, you'd see people writing in the ham magazines about how difficult it was to build at 220MHz. But as the higher frequencies became more common, and devices improved, people would only start to say such things when dealing in 432MHz or higher. In the tube era, things were pretty bulk, not just the tubes but the peripheral components. When transistors came along, things became smaller, and the fact that transistors weren't as heavy as tubes and their peripheral components meant that it was easier to make things smaller. Even forty years ago, you'd have to struggle to get good noise figure in a UHF receiver, scrounging some special part and tweaking it. The devices have gotten better, so at the same frequencies less effort is needed to get to the same level.

As for commercial equipment, I don't think difficulty of construction is an issue. Far more people have traditionally been on HF, hence there's a bigger market. Even if there now may be more using VHF than HF, the needs are much simpler. There will be few working on really complicated antenna systems, so the market will be limited on fancy antenna test equipment.

They can give away cellphones if you sign
up for cellphone service, which should be an indication that it's
not all that much trouble to build at VHF and UHF. A cellphone is
much more complicated than antenna test equipment or a simple transmitter,
yet there is no problem in manufacturing them in enough quantities
that they are given away.

I have a local noise problem I am hoping someone can help me track down. I hear

S-6 or 7 loud, 'coarse' has on all HF bands, on all frequencies, though the intensity of noise diminishes somewhat on higher bands. On 40M, my main band, it is all but intolerable, making QSOs with all but the loudest stations difficult, even at 12 WPM or so.

The noise comes on for exactly 2' 15", and goes off for exactly 1' 25". Over and

over. I have timed it many times over two weeks. The noise is only there after dark. Aha! But I have searched and searched for an intermittent streetlight, to no avail. I have gone about three blocks in all directions from the house in this search, and also looked for automatic driveway/porch lights nearby, but can't find any. What the &*%$ can this be!?? I am really puzzled by the exact timing, since it would seem that a streetlight malfunctioning wouldn't do this, and a driveway light might stay ON for a specific time, but not off! HELP!

Just out of curiosity, do you have any traffic lights nearby. That
is the only item that comes to mind that would stay off for a
specific amount of time as well as on. Here in my neck of the
woods (upstate New York) we have some lights that switch between
timer and sensor depending on the time of day.

It would seem that you have a red light somewhere that is arcing.
Proving it to your local DOT may be more of a challenge than
finding the source of your noise

A dipole can easily be better than a vertical on 75 or 80, depending on what you are trying to accomplish with it! You 40 foot high dipole on 75 meters will make a wonderful antenna on 75 for Iowa from normal W5Land, especially if it is broadside to that place.

On the other hand, the likelihood that you will crack a pileup for Bouvet Island on 75 meters from W5Land with it before you will with the vertical and a decent ground is another issue altogther. The same will likely hold true with woring JT1CO on 80CW, as well.

Each of these two antennas has different strengths and weaknesses on 80 meters. Lumping all verticals, dipoles, paths, directions, and especially those with low take-off and arrival angles together, are simply not a fair comparison or an answer to which one is better.

You have to specify what you want to do with them, and to where you wish to communicate to really do a fail job of making the decision on which one to use.

>than the electronic components.

Fortunately, the component size has been reduced over the years from
tubes to discrete transistors and the surface mount components. Since
there is no longer a need to mount leads through the PCB, the stray
inductance can be greatly reduced, thus, more or less traditional
designs can be used well into the UHF range.

>I guess this is part of the reason
>why there are fewer SWR meters and antenna analyzers commercially
>available for VHF-and-up as compared to HF.

On HF, where the feed line losses are quite low, there is not much
interest in tuning the actual antenna, but instead try to resonate the
combination of the antenna itself, the feedline and the antenna tuner
as a single unit. If you measure the complex impedance at the lower
end of the line, it does not tell much about the antenna terminal
complex impedance, unless you know the exact feedline electrical
length in wavelengths for that particular frequency, due to the
impedance transformation of the unmatched feedline.

On VHF/UHF, in which the feedline loss is usually considerable, the
SWR meter will give smaller indications at the low end of the
transmission than at the antenna terminal, so you must know the
feedline losses to compensate for it. Anyway, due to the considerable
feedline loss is, part of the forward as well as reflected power is
dissipated (into heat) in the feedline, thus, it not a good idea to
match the VHF/UHF antenna with an antenna tuner down in the shack. The
proper way is to match the antenna itself, which requires that you are
able to measure the actual impedance at the antenna terminals. Thus, a
proper VHF/UHF antenna analyzer would have an outdoor unit at the
antenna (a directional coupler with rectifiers) and in-house unit for
displaying of the measured values.

>What does it take to overcome the impact of stray capacitances and
>inductances? More careful construction? Stripline? Anything else?

If you are used to working with complex antenna impedances, adapting to micro striplines should not be too hard. Various stubs can be constructed from sections of PCB tracks. The velocity factor of glass fiber boards are about 0.5, so a quarter wave section is about 90 mm at 432 MHz and 30 mm at 1.3 GHz, so it should be quite easy to work with these. At 432 MHz, the dimensions are of course a bit bulky for portable applications.

An low power amplifier with both 50 ohm input and output impedance can be constructed by first making a 50 ohm strip and cutting it into 4 parts with three cuts. Across the first and last cut, install SMD DC blocking capacitors and at the middle cut, install e.g. a MAR-x series MMIC amplifier and a bias resistor to supply the operating current. Install SMA connectors at the ends of the stripline and you have a modular amplifier with 50 ohm input and output impedance.

You are correct, it is unlikely to be a streetlight.

But there are other possibilities, such as a short cycling heating system,
a streetlight that is timer driven after dark, a defective security light
or anything else on a timer.

You might try taking a simple AM handheld radio, and seen if you can trace
the source.

Probably 82% of my yik yaking is NVIS type propagation. I was once in airforce mars. But I never did anything important while in it. I think the highlight of my mars career was getting free junk like tubes, old GE radios, etc. Some got old collins KWM-2's, but you had to be a bigwig in mars, or be a good brown noser. :(I couldn't take the local politics of mars. Reminded me of romper room sometimes. You had a few that wanted to run the whole show, and got bent easy if you started encroaching on their marsdom. The HF mars was ok. Pretty boring most of the time though. MK

You will probably need to DF it with a portable radio. That sounds
like power line noise, but the timing seems a bit strange for that. MK

A couple of years ago, inspired by a W4RNL web article, I slapped together a 2-meter half square with pvc and aluminum angle stock. I was astonished at the deep nulls along the 1/2 wave element axis of this simple antenna. Would this behavior carry over to a practical HF design?

But isn't your antenna about 1/8 wave up? I had thought that was the height. Even 8 radials is not enough for 1/8 wave up. To equal 120 ground radials at 1/8 wave up, I think you need about 60 radials. On mine at 36 ft up, "1/4 wave" I needed only about 10 radials to equal 120 on the ground. My 4 radials were appx equal to 50-60 on the ground. Your 8, if at 1/8 wave are equal to about 16 or so if ground mounted. I think it's enough to make the difference. But also, Iowa is barely far enough to see a big difference many times. Try a CA. station. I was always 2 s units better to CA. on the vertical no matter what. If your's isn't , it's not working up to par. Trust me. I had times to the midwest when there wasn't much difference. But thats not really the antennas fault. It's just the crossover point where the vertical and dipole are about the same. It's about the same distance from Houston to El Paso as it is from Houston to Kansas City. You don't really think of either as long haul on 40m at night. When you get to about 1500 miles out is where the vertical should start to really shine. Here to CA is a good reliable test. MK

I have measured about 2 S-units rejection off ends of half-square on 20m. I have been using a rotatable half square on 20m for CW sprints using two 20ft fishing poles (Black Widows) on 5ft tripods. Mine is actuallyan Inverted half square with the horizontal wire at the base and fed in the corner. Makes it easy to redirect by moving one of the tripods.

Grounding is a potential problem with diecast boxes because the edges of the board cannot be effectively grounded to the box [1]. Often there are multiple ground paths through the ground lugs of coax connectors and the metal mounting pillars.

Why not mount the board flat down on the base of the box? Because it's generally good VHF/UHF/microwave practice to keep the RF and DC components on opposite sides of the board, using feedthrough capacitors to provide DC power to the RF side. If you don't have access to the back of the board, you have to take much more care to keep RF out of the DC wiring.

Much better are the tinplate boxes we can get in Europe, which have removable top and bottom lids. The PC board is cut to size and mounted part-way up the walls, so you can easily get to both sides. The groundplane is soldered all round the walls so that grounding is excellent. RF connectors come straight through the walls and onto the board, with zero lead length.

The boxes are available in a wide range of sizes to suit various kinds of RF modules, and are mostly made by a small German firm called Otto Schubert GmbH. I don't know if these boxes are imported into the USA, but most European VHFers wouldn't use anything else.

[1] If you really have to, you can bolt a large number of bent-over solder lugs to the box, and solder them directly to the groundplane of the board... that will work, but it's better to avoid it.

The comparison is between a 1/4WL vertical on 40m with eight radials
elevated 1/8WL and a 75m dipole used on 40m.

> Each of these two antennas has different strengths and weaknesses on 80
> meters. Lumping all verticals, dipoles, paths, directions, and

40m DX is generally too weak to copy on both antennas.

Yep.

> station. I was always 2 s units better to CA. on the vertical no
> matter what.

My 130ft dipole is pointed at CA and always beats the vertical in
that direction on 40m. SSB DX on 40m is usually too weak to read on
both antennas. I have never heard any signal where the vertical had
a distinct advantage. I'm considering taking it down because I never
use it except to compare and lose to the dipole. One other
consideration at my QTH is that the ground is pretty bad as can
be seen from the ARRL ground conditions graph.

Automatic Gain/Volume Control. When engaged, it compresses the audio
volume range of signals received so that weak performers and
powerhouses sound nearly the same. This answers your complaint of the
tepid response to otherwise serious change in levels, but is unlikely
to satisfy. Keep the AGC on and observe the S-Meter instead (the
S-Meter is a direct reading of AGC potential in many sets).

Nope, not at all. The white noise generator is perfectly suited -
that is the point of the "noise" in Noise Bridge. It is a source,
nothing else, the remainder of your system already presents the
necessary bridge configuration.

Hi Jason,

And as well it should. This suggests you would feel better with a higher amplitude white noise source. As I said, designing and building a linear amp will test your self challenge. It is not such a difficult first assignment, and neither is it a brush-off.

Greetings,
I bought the new inexpenssive Grundig mini world 100 sw radio
(not bad for 29.95)
portable and want to make it more effective for listening to
the sw talk shows accross the U.S., is there a few choices
for antenna boosters etc to help increase the signal catch,
I have the radio shack sw wire wind up-job that comes on that
pully, it doesn't do much even hanging near the window,
thanks for some suggestions. any active antennas etc or something when
I travel or drive in my car or at home. thanks. even antenna suggestions
for other better portable sw radios.

That certainly was the case with my Novice station in the 50's. But my dipole, which was never more than 10 feet up at the HIGH end, worked well, and from my home in Missouri I worked stations on both coasts on 40 meters running 30 watts input.

Dang that is frustrating! I had a changing buzz I tracked down to a
neighbors
lovely display of hanging Christmas tree lights from a coat hanger. Seems
that Martha Stewart talked them into it. It was the kind of lights that
changed
blinking and fading sequence and until I sat in a chair by the window with a
radio on and watched their lights, I didn't know where the hey it was
coming from.

Try walking around with a small transistor radio. Use it like a tricorder.
When the trouble is located, change the offending chunks back into a gas.

Hmmm... I put up a 40m (2x33.5')dipole for my XYL and it proved even deafer than I am. It was perforce pointed into the Dakotas and So. Atlantic, so I replaced it with a Butternut (vertical), with the dipole's elements part of the ground plane. That worked FB on all bands until one day after a hard rain the SWR went postal, cooking the tubes in her RF amp. So I took the Butternut down for testing and reinstalled the dipole to tide her over. She didn't know a 2x33' dipole didn't work on 20m so she used it with a tuner on 20m to make 72 DX contacts in about 4 hours!! My guess is that the too-long dipole has a cloverleaf pattern on 20 that covers the good DX spots but what do I know? I didn't even know that all DX on 40m was weak til now.

It could be the duty cycle of a motor driven device, a washing machine reversing or a tumble dryer in "anti crease" mode? - modern units use DC motors with electronic controllers but it could still be a bad case of brush noise.
Do you think it's radiated or supply borne - is the problem reduced on a battery receiver?
Good luck
John

Will,

When you claim that the noise is "only at night" do you mean darkness, or night-time? In other words, have you noticed that the noise is starting later and later as the days get longer? If the latter's the case, then it is something driven from an outdoor photocell. Otherwise, it may be some time-dependent activity like the wireless car alarm on the guy across the street who gets home at 6:00pm each night...

Build yourself a coat-hanger RDF antenna and go fox-hunting.

Oh, and be sure to report back when you find it - you've captured my curiosity.

That would be all the more reason I think you don't have enough
radials for the height. I can't believe you never hear dx. I worked dx
on both type antennas. I think you are just not on at the right times,
or places. I guess you can only get it so high at your qth, but it's
too bad because the vertical has never gotten a fair shake. It seems
that going to a 1/4 wave up in height must make a pretty good
difference if you use only a small amount of radials. Heck, when I was
working far off dx, my vertical was usually 4 s units better, not 2,
like when working only 1500 miles. I used to talk to VK land two or
three times a week for a while. The vertical got the same reports time
after time. Always 3 to 4 s units over the dipole. And I was usually
S9 plus. Of course, I was running a KW though. I was working a guy in

Tokyo one time. With the vertical and a KW I was 20 over 9. With the dipole and a KW I was about S8 to S9. Reports from VK were usually about the same. Too bad you couldn't bump it up to 35 ft. I used a rat shack pushup mast to support mine at 36 ft. My comparison dipole, which was 40 meter and coax fed, was on a different mast at the same appx height. I once ran the same 1/4 wave antenna ground mounted with about 24 radials, and I had about the same results as you . Upping it to 36 ft with only 4 radials was like flipping a switch from night to day. MK

5019. The 'talkin'est antenna!

If you are in the market for a screwdriver mobile antenna, then I invite your attention to the
Carolina Cyclone shown on my website below. The difference in the Carolina Cyclone and
some of the others is in materials, workmanship, and price. Often, increases in signal strength
are achieved by increasing the size of the inductor, wire size, and spacing. This is what I have done with the Carolina Cyclone. Cyclone I, for example, is 2 1/2" dia compared to
only 2" for the DK3 clones and uses #14 wire spaced at 8 turns per inch for a better form
factor. Materials are black Nylon, the same materials used for Nyloc bolts, to handle high
power, and give rugged service for years and years. The result is 800 watts power handling
power (conservative) for Cyclone I and a full 1500 watts SSB for the Cyclone II, which is
a full 3" diameter to give the same "Q" as the famous Texas Bugcatchers. You will find that
you will be most successful with DX and pileups with the Carolina Cyclone series of antennas. AND the prices are well under those of most of the competition. For more details, please visit www.qsl.net/k4kwh .

Or just drill screw holes every few inches when you mount the board in
the bottom of the chassis. In practice, I usually find that 6-8 around
the periphery of a 4x2 board is fine. The screws, plus the grounding
lugs of any SMA jacks and feedthrough caps you're using, will generally
be enough.

I use a quad mag-mount successfully on all bands from 440 MHz to 40 meters with the ATAS-100 and my Yaesu FT-847. I have been using this configuration successfully on a Ford Explorer, a Ford Expedition, a Ford Taurus, and a Lincoln Navigator. I have had excellent signal reports and the ATAS tunes successfully on all bands without auxiliary grounding. I just stick the antenna on top of the mag-mount and it seems to work just fine.

Can the Icom (or any) auto tuner be used in a hot ventilated attic?
I've seen many posts from people who have done so. I live in Maryland,
the summers are hot, and I can't help but believe attic temperatures can
be excessive to the microprocessor in the tuner.

TIA.

Andy N3LCW

5025. Icom AH-3/AH-4 compatible?

Will:

While I am a little puzzled by the exact timing, I can tell you from personal experience that a non-functioning Sodium Vapor light* has exactly the characteristic you describe, while remaining dark. I have second hand information that a mercury vapor light** does the same, but I am not sure about it remaining dark while emitting noise. The trick is to ignore illuminated lamps and look for those not on.

The noise producing mechanism is the starter attempting to fire a non-responding lamp and thermally cycling off, then cooling and starting over.

Someone else asked whether this is starting later as sunset gets later. This will define whether it is photocell or timer operated. If you can hear it on VHF at all, get yourself a VHF AM receiver and directional antenna and go after it. FM won't work. Trying to find it on HF will drive you nuts, as the antenna characteristics of whatever wiring is connected to it vary for many reasons, and the strongest signal will not necessarily be anywhere near the actual source.

I have seen the AH-4 mounted on the outside of a motor home on ladders,
in the trunk of a car, and at the bottom of an antenna tower.
In all examples the issue may be with temperatures.
I would check the manual or send Icom an email and
see what they think.

I don't think I would put it in my attic here in Atlanta, Georgia
with temperatures that reach over 120 degrees..

Well, if you could locate the tuner close to a soffit vent around the edge of
the roof, and you have decent exhaust vents above that to get some circulation
going, it should be okay. Put some ridge vents in, if you can, and you shouldn't
have a problem at all.

I'm going to be installing my Perth outbacker mobile antenna to my 98 Ford Ranger truck. I have two options that seem best to me. Mounting it to my rear bumper near the corner. Or, mounting it to my trailer hitch receiver, by removing the ball. Making an adaptor plate and mounting the OB-SB perth mount in place of the ball.

Any comments or suggestions to what would be the best option to mount this antenna and OB-SB mount to my truck. Thanks in advance.

I run a Cushcraft R-7 vertical (40 thru 10m) which is a half
wave
configuration and does not require a ground. I'm very
pleased with
it. I picked it up used very cheap -- check around.

Personally, I would mount a Perth inside my garbage can. :-) What I did for
my screwdriver is to mount some 5/8" threaded stock into the trailer hitch
hole and fasten the antenna mount to that threaded rod.

Now I don't know why you would mount it in a garbage can as that would tend to shield the RF and screw up the wonderful DX properties of the antenna. I have mine mounted onto the crossmember of my aluminum ladder rack on an Astro van and I work Europe, Africa, Japan, etc. with ease with only 100 Watts. The Perth (Plus) has even given my Alaska on 60M with 50 Watts. If you dont mind holes, you might mount it on one of the siderails of the box near the rear to keep it as far from the cab as possible. I can send you a picture of my Astro setup if you wish. I think the best is to keep it as high and in the clear as possible. If you have a topper, you could add some aluminum ladder racks, one on the cab and one on the topper. Put the antenna on the one on the cab and drill a small hole in the roof to attach the ground wire directly to the top of the cab with a 6-32 or 8-32 machine screw/washer/lockwasher/nut. Be sure to mount it as far to one side or the other so you can reach it to unscrew it to change bands!

I can't tell you exactly the amount of loss per trap but there is some.. I
would more worry about the losses in the radial system . You did not mention
how you plan to mount the antenna Ground or above ground? I would take a
look at the Butternut verticals. Also we could give more accurate advise if
you mentioned what your goals in operating are do you just want to get on
the air.. or are you more interested in 80/160M DX .
73 Dave kc1di always qrp..
P.S. I avoid traps as much as possible but then I use 2watts or less power
if your running a Kilowatt traps may be fine for you. Also some of the non
trap designs can be just as lossy.

Lots of heat in attic all right. As an example, I floored a portion of my
attic for storage years ago (when I was relatively young). It was summertime
and hot enough up there to rouse my curiosity. I brought up a thermometer to
see what temp I was working in and it was running 130 degrees. This was in
north Texas,
but on an august day in Anywhere, USA I'd expect pretty high temps.

Yes, it would. That is why I said it would be OK for fixed operation.
You could orient it to give the best signals. This would be an
inconvenience for mobile operation.

Loran C is used for other things besides navigation. It is also used
as a frequency and timing reference and gives better results in some
parts of the world than if you used WWV. I have seen small loops (2-3
feet across) used for this.

Going from best to worst, the timing and frequency references
available for the home experimenter (that is, they are 'affordable')
are GPS (UHF), Loran C/WWVB (LF/VLF), and WWV (HF).

Since WWVB upgraded their station a few years ago, they are alleged to
have a good signal over the entire USA and most of Canada. If I were
to homebrew a frequency/timing reference I would use WWVB.

Hmmm, interesting. The two shields are insulated

I think it depends on the application.

I have seen cases where the inner shield is connected to 'circuit
ground' and the outer is connected to chassis ground, and sometimes
the outer is connected to chassis at one end only. This helps
eliminate circulating currents and external noise pickup on the
'circuit ground'. This applies to both coax and twisted pairs.

If you are going to use it as a cheap source of coax for radio use,
just connect them both together.

I looked at the article again. No web references.

After studying the pictures a bit I will attempt another ASCII picture
of the feed point. This is a close up of the feed area in my other
post.

```
---------------------+----------+
| |
ccccccccccccccccccc |
s | |
-----------------s---(----------+----------------
| |
| |
| |
---------------------+----------+
```

S is the shield of the coax and is connected to the mast at the feed
point.

The center conductor is connected to the downward hanging wires, all
four of them even only 2 are shown here. The center conductor is not
connected directly to the mast.

In discussing receiving antennas for Loran-C, the subject turned to loops and whether their bidirectional response would be a problem. Jim, N8EE, wrote:

> Yes, it would. That is why I said it would be OK
> for fixed operation. You could orient it to give
> the best signals. This would be an inconvenience
> for mobile operation.

I wonder if the crossed loops used for LF direction-finding might work as a non-directional magnetic antenna for this application. The outputs from the two loops would have to be phase-shifted 90 degrees relative to each other before being summed together, but the result would be similar to that obtained with crossed horizontal dipoles phased to produce a turnstile antenna.

The obvious problems are: (1) How to achieve the desired phase shift over the considerable bandwidth of the Loran-C signals without degrading the waveforms and (2) How to get enough sensitivity from the loops since they will have to be untuned to span the instantaneous bandwidth of the signal with no phase distortion. Both of these problems can be addressed with conventional circuit design techniques.

An aircraft implementation could take the form of crossed ferrite loopstick antennas, or orthogonal windings on a single rectangular slab of ferrite. These could be placed in a shallow cavity in the bottom of the airframe with an opening to the outside world through a radome, again, following established practice with LF RDF antennas.

Somebody probably already makes such a beast, I suppose, but I haven't seen any discussion of it.

I am supposed to be part of that group.
Unfortunately we've not yet found an agreement between us about how we should do the tests and what we actually can reasonably do.
Another thing that is slowing the whole test setup is the fact that the ones of us that tried to build the EH found that it isn't working as claimed (or we are just unable to build it), so the interest isn't so high after all.
I'm sorry to say this, but I admit that probably I'm not the right person who can set up a well made test. However if anyone wants to help, please contact me.

> S-Meter is a direct reading of AGC potential in many sets).
>
I have been using the S-meter more than my ear, as it takes a low SWR
to make the difference clearly audible. But I don't like the S meter
on my Kenwood TS-430S. It resembes a shrunken version of the
speedometers of some 1960s and 1970s GM vehicles like the one on this
1969 Cadillac
(http://kevingilligan.tripod.com/sitebuildercontent/sitebuilderpictures/inst.jpg).
Imagine that the Cadillac speedometer is shrunk so that it is just 1
inch in diameter. Then imagine that the marks for x5 mph (05, 15, 25,
35, etc.) are taken out. You'd have difficulty telling whether you
were driving 53 or 57 mph. This should show you why I don't like the
S meter on my rig. S5 to S9 is the middle of my S meter, and the
marks are so close together and make it difficult to notice subtle
changes. The area beyond S9 is difficult to read, because each
marking represents a 20 dB change instead of the 6 dB typical for the
S1 to S9 area.

With the 20 dB attenuator on, I usually find that the noise bridge
gives me an S9 reading for a mismatch and an S5 to S7 reading for a
match. Because the bandwidth is so narrow on the lower bands, I
sometimes overshoot because I miss that QUICK null. If I had to rely
on the S meter, I'd rather have a mismatch correspond to S5 and a
match correspond to S1 to S3, as the meter is easier to read in this
region. Also, the audible noise level difference would be more
noticeable.
>
> And as well it should. This suggests you would feel better with a
> higher amplitude white noise source. As I said, designing and
> building a linear amp will test your self challenge. It is not such a
> difficult first assignment, and neither is it a brush-off.
>
OK, I see what you are getting at. I want an extra amplifier built-in
to strengthen the noise source. The reflected component of the
received signal resulting from the noise bridge would dwarf the low

band spikes I have been complaining about. I'd also want to put in an attenuator to avoid overloading the receiver. Since I'm stuck with my lame S meter (as I don't want to add the complexity of a frequency control to the noise bridge), I would also want to make the amount of amplification and attenuation adjustable. Thus, I can make S5 the mismatch noise level and S1 the match noise level instead of S9 and S5.

To distinguish between an SWR of 10 and an SWR of 100, I'll probably need some type of differential amplifier in the circuit. I have noticed from the equations that the reflected voltage for an SWR of 100 is not much higher than that associated with an SWR of 10. So I think I can use a toggle switch to activate such a differential amplifier. This will allow me to easily see that I'm getting closer to a match on 80m, even if my SWR is still 5-10 or more.

By the way, Richard, thanks for your comments. I have a better idea now of just how a noise bridge works.

Jason, my suggestion would be to connect a sensitive AC voltmeter across the speaker output of the TS-430 and do the following:

(1) Crank the RF Gain control completely counterclockwise (ie: full off)

(2) Crank the AF Gain control completely clockwise (ie: full on)

(3) Turn on the Noise Bridge and adjust the AC voltmeter sensitivity and RF Gain until you have full-scale meter deflection and a comfortable listening level.

(4) Tune for a null. A 6 dB reduction in bridge output will now correspond to a reduction in meter deflection to half scale. If, as you approach the null, you find you need more sensitivity, adjust the RF Gain upward so that the meter is once again at full scale and continue.

(5) Ignore the S-meter entirely (of course).

Hi Francesco,

This is not news. The last discussion was that Stefano would PROVIDE
a working model. It comes as no surprise that he could not. No doubt
we will find him re-appearing with the same happy news of the
blessings and bounty that come to those who build one - which of
course ironically suggests that Stefano is un-happy, without blessing,
and impoverished (already admitted to, in fact).

As I put it to Stefano some time ago, he appears to be wholly unsuited
to the task of explaining, fixing, building, or championing the EH
antenna. His posing as an itinerant vegetable peddler with the homesy
aw shucks mentality to spin a yarn about the glories of this antenna
just doesn't cut it. I put it to him that he should instead step down
as spokesman to allow someone better educated in these matters and
certainly a better technician than him to do the job right.

Francesco, in spite of your self doubts about your ability to test
this, it appears that your intelligence easily eclipses the EH
community.

However, as a test at the most fundamental level, the EH clearly
failed:
>ones of us that tried to build the EH found that it isn't working as claimed
and the EH crowd could do nothing better. They have no one to blame
but themselves (if in fact they cannot accept their darling EH is
DOA). There seems no reason for you to pursue this further if they
cannot motivate themselves beyond braggadocio.

>Jason Hsu, AG4DG

Hi Jason,

I see no reason to add or use an attenuator, there is absolutely no problem with overloading the front end. Your source may effectively provide a fraction of a Watt in power, but the band pass filters of your TS-430s (same one of two HF rigs I have, the other is a Drake TR-7) easily pushes down the amount of power applied to the first mixer to a level of microWatts. In fact, it would be a paradox to build an amp for the white noise source and then attenuate it.

The simple solution would be to tap off that S-Meter voltage and feed it to a VCO in the audio range that in turn drives a separate speaker (or mix it back into the audio chain through a special switch). This is a very cheap design that could be accomplished with the venerable 555 timer chip, or with the already mentioned VCO's which would interface easier - perhaps.

This would give you a variable tone whose frequency is driven by the S-Meter level. By Adjusting the top end frequency and bottom end frequencies of the VCO to match full scale deflection and no deflection, you will find that your ear does far better in resolving differences that escape your notice by viewing any size meter.

As for your complaint that you sometimes miss the null because it is so sharp, you are arguing the opposite. When I use my TS-430 for bridge applications the nulls easily plunge 100dB; what you describe seems to be a tepid 30 or 40dB at best (if then). This is not your fault, it simply an illustration of balance, bandwidth and isolation (which you may be suffering from the lack of). If I were to use my own idea of the whistling S-Meter, the 100dB notch would sound like a low thump in a warble, as I traversed it. If I inverted the voltage to frequency conversion, it would be a quick high chirp, or click, in a field of rumbling. The occurence of either of these two indicators would be enough to cause you to tune back and peak the response. For anyone who has tuned SSB, it is more than obvious how much difference several 10's of Hertz can make. The ear is a very good discriminator. With a full scale equivalent at 1000Hz, this would be the log equivalent of less than 5% resolution, something entirely lost in a 1 inch meter.

Hi Jim,

Often when there are two shields provided for in a circuit, one is
driven to increase the input stability. However, this is not a
suitable application for our interests (such designs rarely emerge
above 1MHz in instrumentation applications).

Two shields are often used to isolate grounds without losing
shielding. This is exceptionally difficult if other grounding issues
are not resolved (this technique is the fine tuning, not the
powerhouse solution). As such, recommendations to connect the shields
together at both ends is best.

Message-ID: <3C8FA6B2.7E330CB9@IEEE.org>
Source record: 146751

I can't find my last posting on this subject. The reason that I elevated my radials to 20 ft on my 40m vertical is that EZNEC indicates that is the point for maximum gain (0.13dB) at a low TOA (18 deg). As the radials are elevated above 20 ft, EZNEC sez that the major lobes assume larger take off angles (40-50 deg).

Based on my testing, my 33ft vertical with 8 radials elevated to 20ft very rarely beats my one wavelength dipole on 40m for contacts within the USA. That includes directly off the end of the dipole. In other words, for my applications, the vertical is virtually useless and is in danger of being taken down.

Ivan,
Probably the basis for almost all mobile antennas is
a 1/4 wave vertical, or a 'shortened' 1/4 wave vertical.
It depends on the frequency range of use. On the lower
HF bands, a shortened 1/4 wave antenna is the usually
antenna. Toward the high end of the HF bands a 'full'
length 1/4 wave is common. From VHF and higher, almost
any electrical length antenna can be used, or antenna
arrays.
For the radiation patterns, gain, etc., you might get
one of the antenna modeling programs and 'roll your own'.
Until you get into the VHF region, very few mobile antennas
have any gain (more like negative gain!). The radiation
patterns are so variable, depending on installation and
location, that a 'generic' pattern for a particular type
of antenna isn't even close at times.
Good luck with your research, and have fun...
'Doc

5065. 50ohm Coax + 6:1 Transformer or 300ohm Balanced Feeder?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-13 19:47:58 UTC
From: JRW <freeboy@ic24.net>
Message-ID: <u8vcav6tkgbc58@corp.supernews.com>

Hello,

I have, on my computer, designed a triangular loop antenna with a feedpoint impedence of 300ohms. In the position I want to install this antenna I have another antenna which I want to remove. The old antenna is fed with 50ohm coax.

The new antenna has an impedence of 300ohm at the feedpoint, I could therefore either feed it directly with 300ohm balanced line, or I could use the existing 50ohm coax feed with a 6:1 matching transformer OK?

Would the two methods work as well as each other or would the 6:1 transformer have greater losses than a straighforward 300ohm feed? By the way, the coax is RG58 and the length of coax is about 20ft.

The antenna is for 10m band and I intend to use a power of 10W PEP and occasionally use 100W PEP.

John

> You could orient it to give the best signals. This would be an
>inconvenience for mobile operation.

?? Loran C consists of a bunch of transmitters located all over the world, so orienting a directional antenna to maximize signal strength from one transmitter would of necessity result in minimizing the signal strength from others. No matter what your application you almost always want to receive signals from several Loran C transmitters at once, which is why omnidirecitonal antennas are pretty much exclusively used.

>Loran C is used for other things besides navigation. It is also used
>as a frequency and timing reference and gives better results in some
>parts of the world than if you used WWV. I have seen small loops (2-3
>feet across) used for this.

While you could in principle extract frequency from a single Loran C transmitter, there are reasons why you are always better off tracking several. Any single transmitter can fail, or be taken off line for maintenance, so tracking several has a reliability advantage. There are also errors from propagation effects which can be at least partially mitigated by using ensemble averages of results from several signals taking several paths.

More that this, extracting really accurate, independent time-of-day information from Loran C inherently requires solving the navigation problem in any case. That is, navigation requires reception from at least three transmitters since it needs to solve for 3 unknowns (longitude, latitude and time), so determining time information is essentially the same problem as determining position. In fact if you want your clock to produce an accurate second pulse on-time with UTC you'll need to be tracking several chains (each chain has 3-to-5

transmitters) at once. All of this makes an omnidirectional antenna attractive even if you are sitting still.

So while I've seen a lot of Loran C receivers used for time synchronization in telecommunications networks (it was the standard method of doing this in the early 1990's, and is a frequent backup for GPS now) I've never seen one that used a directional loop, as opposed to a whip or a vertical H-field probe, as an antenna. I've seen loops used for WWVB a lot, but the quality of time and frequency from that source isn't even in the same league as Loran C. Loran C can provide near-GPS quality if processed correctly, and outside the US has the additional advantage that other countries often own their own Loran C transmitters while GPS is controlled by the military of a foreign power whose interests are not always guaranteed to closely match thier own. And while inspection of

http://www.locusinc.com
http://www.megapulse.com

shows that loops have become trendy for Loran C reception very recently they always use a pair of loops crossed at 90 degrees to retain the omnidirecitonal reception.

>Going from best to worst, the timing and frequency references
>available for the home experimenter (that is, they are 'affordable')
>are GPS (UHF), Loran C/WWVB (LF/VLF), and WWV (HF).
>
>Since WWVB upgraded their station a few years ago, they are alleged to
>have a good signal over the entire USA and most of Canada. If I were
>to homebrew a frequency/timing reference I would use WWVB.

I would too if I were homebrewing, because it is the simplest processing problem, though I'd still note that Loran C is likely to be a much easier reception problem. There are likely to be Loran C transmitters closer to you than WWVB, and because the duty cycle is so low the instantaneous transmitted power is huge (many Megawatts). I'd also point out if you draw these on a scale of quality of the result these would look much more like

|----|----|-----------------------|----------------------------|
GPS Loran CDMA WWVB WWV
C

That is, when absolute time accuracy on the order of 100 ns is routinely available, the several millisecond relative propagation delay difference between WWV day and night paths looks awfully sloppy. If I were buying I'd certainly buy GPS. Not only is it the best quality but most of the complexity has disappeared into ASICs that are very cheap in the volumes GPS sells at. Of course, the very easiest precise time and frequency source to buy and use is often CDMA (see

http://www.endruntechnologies.com

for example) since it requires no better antenna, and antenna placement,
than your cellphone does.

John,

If you are not too particular about algorithms based only on frequency spectrum, the following paper has a couple of algorithms using neural networks. The same authors also have a book on the subject (See the references). Hope this helps..

A. K. Nandi and E. E. Azzouz, "Algorithms for Automatic Modulation Recognition of Communication Signals," IEEE Trans. on Communications, vol 46, pp 431-436 April 1998.

I would try for at least a quarter wave, if possible. There is a
program called sidemount.exe that you can download at
www.rfglobalnet.com. The program simulates the effect of sidemount
antennas. It is a dos based program and you will need to register with
rfglobalnet to get it.

I'm thinking of putting up a sloping dipole for 40 meters vs. a vertical for that band. The area I want to cover is the East Coast US from the West Coast US. Am I right to assume the sloping (In the direction of desired coverage) dipole will be a better radiator? Assuming the vertical at 20 feet and the dipole sloping from 40 feet to 15 feet?

FWIW, I bought a nearly free marine Loran C receiver, and would like to
use it as a cheap-ass GPS, until Loran C gets shut down at least. Afterward,
I have a case,display and keypad to use for microcontroller projects.

How about getting a piece of square steel tubing from a welding/
fabricating shop that will fit in the stake holes in the box. Have them
weld a plate to the top of it. You can paint it to suite, drill a hole
for the antenna mount. From there mount the antenna to it and put it in
one of the stake holes in the top of the box (may need shims to hold it
tight). Attach the coax and a ground wire for the antenna and your off
to the races. I would suggest you put a separate ground from the plate
to the box as well

Oh, you might want to look into guying the antenna if it wips around too
much, mine does.

According to modeling, just about all sloping does is lower the gain and
increase the NVIS radiation in the direction of the slope. Most of the
radiation will still be broadside.

Hi Rod,

I saw this demonstrated at the Mike & Key Amateur Radio Swap Meet (Washington state) just last weekend. Fairly simple in concept without the added folderol of needing special math and new physics to explain its operation.

In a nutshell, it presents you with two fixed length non-conductive tubes as elements on a fixed length boom. The tubes allow a flexible copper bus strap to be fed into it by computer controlled stepper motors. Thus, all elements can be set to a specific length to match the requirements of operation. However, given that the boom and distance between the forward elements and back elements are all fixed, there is obviously some compromise on optimization.

I didn't ask the price, but their page reveals it is quite expensive.

I don't think it's a problem until you start approaching a 1/2 wave or
so up. The pattern is quite nice at 1/4 wave up. And in many cases,
the "theory" about takeoff angles doesn't mean doodly in the real
world. If ground losses overshadow a better takeoff angle , then it's
a waste trying to get the "best angle". I've seen many ten meter
verticals that do better the higher you place them, no matter what
theory about high angle radiation at high heights say. But the main
problem you seem to have is not enough radials for the 1/8 wave
height. Thats really the only way I can explain the differences from
yours to the one I ran.I know from testing that the 4 radial GP at 1/4
wave works much better than at 1/8 wave. The reason I tried it was I
was doing antenna work, and had my mast lowered about halfway one
night, and I tried the antenna. It wasn't near as good.
>
> Based on my testing, my 33ft vertical with 8 radials elevated to 20ft
> very rarely beats my one wavelength dipole on 40m for contacts within

> words, for my applications, the vertical is virtually useless and is
> in danger of being taken down.

And it probably will continue in this vein when you run the equal of
about 16 radials on an equal ground mount system. You need about 30
radials to equal the antenna I used with only 4 radials. "at 36 ft
up". And my ground may be a tad better to boot. I wouldn't be worried
about it too much normally, but I'd hate to see people get the
impression that these antennas don't work just because you don't want
to use the proper number of radials for the low height. Or raise it up
to get by with a low number of radials. Obviously from the good
results I had, a 1/4 wave up must be a pretty good place to be, and
indeed the modeling shows it to be fairly clean with little high angle
stuff. But if I had my way, I'd be even higher, to heck with what
modeling says about it's high angles.I would be willing to bet money
in almost all cases the higher antenna will be best regardless. The
ground losses will be lower, thats a given. MK

The big question is always the environment. After reading all about ground conductivity, I ask what about a grove of trees 50 feet tall which are heavily populated with leaves. Actually, many acres of trees, not just a grove, and with varying heights from 20 to 50 feet. Are they absorbers? A reflective surface? If so, where is the surface defined? At the extremities of the leaf ends? Or at the point of maximum RF conductivity? I know the Vietnam experience with HF below heavy vegetation was bad, but what about above? I can easily understand why no one wants to rigorously address the issue, but it makes answering questions about one antenna versus another impossible to answer in the general case.

I can explain this parodox. The amplifier would ensure that the
reflected voltage is strong enough that those darned noise spikes
don't foil my efforts to find the null. The attenuation would be
adjustable. I'd like the noise level corresponding to a mismatch to
be S5 instead of S9. The S1 to S5 part of the S meter is easier to
read than the S5 to S9 part.

>
OK, I guess I didn't express myself right when I said I missed the
null because it was so sharp. Actually, the null was VERY narrow.
When I tune on 80m, it's easy to miss the null. For my DK3
Screwdriver antenna, the SWR doesn't decline all the way to 1.0 on
80m. I can only get it down to 3-5, and the S meter doesn't move that
much to get here from high SWR values.

I have not tried it, but I understand that pulsing the power to the
noise source a couple times a second makes the bridge noise more readily
distinguishable from the normal band background noise. This aids in
tuning for a better null, especially in the presence of band noise.

Source record: 146676

Which is better for 6m 2m 440MHz?
A square loop or a round loop?
Is a square loop or a round loop just a dipole 'bent'?
What are the pros and cons of a horizontal vs. a vertical loop?
For a loop should the TOTAL length be 1/2 or a full wavelength?
How do you feed them (and not with food or your hands either please)!?
Why do some people insist the a Square loop should be 'fed' at a corner rather than in the middle if one 'side' of it?
How do I match 50 OHM coax to the loop?
What is the impedance of a loop and what changes it.
People talk about 'nulls' with loops but if the entire loop radiates why are there any nulls and how do you re-shape a loop to get rid of nulls?
What would change with a loop antenna if you added more 'sides' to it until it was a circle? IE- if the loop was 3 sided, than 4 sided (square), then 5 then 6 then 7 then 8 ect........? Would this affect the nulls or impedance?
If I make a square loop out of copper plumbing tubing does the wall thickness or diameter of the tubing affect the antenna?
I have seen 'eggbeater' antennas. Are the dipoles whose ends are bent (like a square or circular loop) but are not on the same plane?
If so is an eggbeater antenna directional.
All eggbeater antennas I have seen are vertical what if you 'lay' them on their side? (don't answer they goto sleep either!)
I need more info on loop antennas but when I search I find a bunch of 'receiving loop antennas' for short wave and none for transmitting also they are all several turns of wire around a form not just a single one I am looking for information about.
Please help me?
I know there are LOTS of antenna software out there but are there any specific for loops and helping me design them?

AND THANK GOD FOR NEWSGROUPS AND SPELLCHECKERS!

Source record: 146678

Traditional horizontal VHF/UHF loops are shortened dipoles bent into a circle or square. Because the current decreases out from the feedpoint (even when the dipole is capacitively loaded at its ends) the resulting pattern is eggshaped- typically by approx 3dB- whether it is a square or circle. A few years back a manufacturer released a full wave loop for 2M- a full wave loop has a pattern very similar to a dipole- i.e. 2 deep nulls- and a bit less gain than a dipole. It did not last long in the market.
One halo 6M antenna from several years back radiated as much from the feedline as it did the antenna- no balun.

Two antennas offer a nearly perfect omni patterns- big wheels and the PAR Omniangle- a .7 wavelength triangular antenna.

Slightly cheaper on 80 meters, ususally, than, say, four 180 foot towers for what is really needed for some paths. Or even two such towers if only two general directions are really important.

Of course, there is also the issue of having only one such tower if you want to use it for the apex of a couple of decent inverted vee dipoles on 80, but, in general .. that still costs more than the radials, no?

You can do a BEAUTIFUL job on 80 with dipoles, W8JI is a wonderful example of that as well as a number of other very carefully thought out and well financed horizontal low-band antenna efforts which are designed for serious long-haul, low-angle requirements.

For the average person who wants long-haul other-side-of-the-world performance, those 30 radials are likely far more effective than any corresponding height horizontal array on 80. At least in most average medium ground conductivity locations that will be likely true.

It also may be that the horizontal lower array looks down over a wonderful valley broadside it on each side. That too makes a lot of difference!

It also holds true that low band HF in the middle of, say, the Sahara Dessert, is going to be a problem, no matter what, no? Even if you are on top of a delightful sand dune that looks down into a wonderful valley of more sand dunes for miles and miles and miles, no?

;)

Did you compare the EZNEC model of your 40 meter one wavelength dipole with the EZNEC model of your vertical? Are the actual results you are experiencing vary from what you expected based on the EZNEC model, or do your experiences confirm the EZNEC model? If they vary from the model, by how much do they vary, and what can be learned from that--not to trust the model? Or that the model is only a rough approximation? BTW, how high is the 40 meter dipole?

Why am I not surprised?

I was at the University of Colorado at the height of the "'60's" (which really got going about 1968). In the expansive spirit of the times and the general liberal attitude of the university and local community, the university sponsored a series of lectures to give "alternative" points of view a forum. I recall attending a lecture where a perpetual motion machine was presented. Magnets seem to be a perennial favorite of the perpetual motion crowd, since they can pull things without an obvious source of power, and this particular machine featured quite a number. They were along a long continuous belt, that turned a wheel as it moved. I recall that the lecturer was appropriately convincing with his almost-right science, but don't recall the details of operation. Anyway, came the demonstration, and gee, whiz, it slowed down and stopped after a pretty good initial run. Ah, but this is just a prototype, the inventor explained. All that's needed is enough funding to make a bigger one, with more powerful magnets. Because, you see, it almost works now, so all it needs is more powerful magnets, and then!

Well, I guess he never got his magnets, because here we are still paying good money for power.

So, best luck to Stefano in his search for more powerful magnets. Just a little more powerful, then we'll have it. Right?

Thanks, Francesco, for attempting to inject some rationality into this morass of bafflegab and hype. But you see, it's a fool's errand. My money says that like the perpetual motion machine inventor, Stefano won't ever find quite the right magnets.

5094. Re: 50ohm Coax + 6:1 Transformer or 300ohm Balanced Feeder?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-14 08:53:53 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C906521.32DF13F@eznec.com>
Source record: 146682

If you've got a modern rig, you'll have to transform the impedance to 50 ohms somewhere, either at the antenna or at the rig. A decent balun will have negligible loss, so that's not an issue. Your choice is to put the balun at the antenna and use coax, or put it at the transmitter and use twinlead. I'd use coax, simply because I don't have to keep it away from metal objects or the ground, I can coil it up, run it through walls, or whatever. It'll have less loss than the twinlead when it's wet outside -- but it's wet outside a lot around here, and the amount of loss you'll get in 20 feet probably won't be noticeable with either feedline, wet or dry, anyway. So it's really a toss. Neither choice will be significantly better or worse than the other.

Just to clarify, Stefano assured us that he will provide the working
EH. We just didn't find an agreement on how, where and when test
Stefano's antenna; again the missing agreement is between the
testers, not between us and Stefano. The test group itself is probably not
enough motivated, since home made antennas didn't show the claimed
behaviour. As full-time employee we often have spare time for our
hobby only during the weekend, so if something isn't enough
interesting probably we take too many weekends to get it done.
However I'm not saying that we aren't going to test the EH
made by Stefano, I didn't give up, not yet at least. I'm waiting
for spare time to be really "spare", and probably other "testers"
are in the same condition.

Well, actually I didn't do anything yet. All I'm doing is gather a bunch
of persons, amateur radio operators hobbysts that also happen to work
in the electronic, telecommunication and physic field and test an EH
made directly by Stefano with our methods and instruments.
What's going wrong in this testing project (probably) is that some of these
persons already built EH prototypes and found nothing good with them.
Probably then these persons lost most of the interest in testing
a "real" EH.

5098. Re: Vertical without a ground

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-14 12:42:03 UTC
From: Val <nishikeit@zilch.com>
Message-ID: <3C909A9B.4FBC9514@zilch.com>
Source record: 146686

Let's clarify:

NO antenna can work without a ground. Period.
Not even in satellites (but, when one use the word "ground"
in this context people tends to get very confused..).

The question HERE is: Can I use a multi-band verical antenna
without countepoids. The answer is simple, but confusing:
No, You can NOT.

But, You can buy a vertical dipole (such as the Cushcraft R8),
where the couterpoid IS the lower (electrical) half of the, at
least in principle half-wave dipole. (think of it as a GP with
one radial, where you pint the radial dow instead of 90 degrees).
This antenna will work excellent. But a ground You have, but it is
the good ole earth ground, which You thread when You are out
trekking, or simply walk from Your door to Your car.

Now, let's talk about efficiency, and NOW it is getting tough.
The Cushcraft R7 will NOT work as good on the lower bands as
e.g. a Butternut (equiped with the correct counterpoids), even if
they had equal length. This is the price You pay for removing the
"earth plane". The R8 need to be shortened to a larger degree on
40 mtrs than the Butternut, in order to keep the size down- A non-
shortened dipole on 40 m is 20 m (approx 65 feet). A non-shordened
GP is 10m (approx 33 feet). The quota betwen the non-shortened length
and the actual shortened antenna length sets the efficiency of Your
antenna (not so easy to calculate as just the quota, though).

For example, the ultra-short MFJ1796 has an efficiency of about 11%
on 40 mtrs. 100W into the antenna is barely 11W radiated power (this
is of obvious reasons not printed in the MFJ catalogue...)

I am NOT working at marketing dept. Butternut. I am NOT telling You
not to buy a Cushcraft (or MFJ) antenna. They are GOOD antennas,
given their SIZE. I am a HAPPY owner of a Cushraft myself - it was
the best way to go QRV on 40, GIVEN NO COUNTERPOID SPACE AVAILABLE,
even if the efficency is about 50%. But I AM telling You: There IS
nothing like a free lunch. You have to pay the prize for putting up
an antenna with space restrictions, wether it is on height or counter-
poids.

[Of course one CAN use a CB top loaded whip for 6 mtrs. But I would
not do it. You'll have to feed it in on end, it would act as the
good ole "end-fed Zepp", but vertical. Some HF amateurs with very hard
restrictions use this kind of antenna (they simply pull out some

wire from the balcony, hanging DOWN, feeding it in the upper end)
The matching thingamajig would be, well, not the surpreme easy one
as the impedance of an End-fed Zepp in reconance is some 3000 ohms or
even more. The antenna will radiate to an extent also without counter-
poids, but my suggestion is to make eiter a verical dipole or GP]

If the antenna and feedline are completely balanced and symmetrical (like an ideal dipole fed with twinlead) and floating in interstellar space, then where is the 'ground' ?

I will have 100 ft of RG-8X between my all-band dipole (Alpha Delta DX-LB+) and my TX. I will be installing a ferrite toroid with 10 turns of teflon coax as a choke. I was going to install the choke at the feed point, but this turns out to be a very inconvenient spot. Eight feet away from the feed point is much more convenient. Will moving the choke that far from the feedpoint compromise performance?

Well, It will act as an efficient quarter wave antenna on 10 meters, and
will have a significant aperture on 12M, 15M, 17M, and 20M, providing the
potential for radiation on all these bands from the feedline. Besides that,
it won't make much difference on 30, 40 or 75 meters.

> the 40 meter dipole?

The dipole is 130 ft long up at 40 ft. On 40m, it is one wavelength long.
The vertical is 33 ft long with eight 33 ft radials sloping down from the
20 ft high feedpoint. I put up the vertical to fill in the gaps predicted
by EZNEC for the one wavelength dipole (off the ends). But that didn't
happen. The noise level using the vertical is two S-units higher than
the dipole. After months of comparing the two antennas, I have heard
two or three signals that were stronger on the vertical but they were
copyable on the dipole because of the lower noise level. On the average,
the signals using the dipole are two S-units higher than the vertical.
The vertical doesn't add anything to my capabilities.

I don't know why the one wavelength dipole performs so well off the
Northwest end. The fact that the land slopes downward toward the
Northwest from my QTH may have something to do with it. Ground
conductivity around here is supposed to be 4 millisiemens per
meter which is pretty low.

To answer your question: Either the one wavelength dipole is performing
better than EZNEC predicts or the vertical is performing worse than
EZNEC predicts (or both).

What's wrong with this? A negative test result is just as valid as a
positive test result if the tests are done correctly.

The point here is that there is really nothing [new] to the EH antenna. The
tests do not validate the claims of the EH "inventor" because the claims are
not valid. Seems like a successful test to me.

Are you referring to the eight ft of coax between the feed point and
the choke? If so, is it bad to have a little radiation there? Will
it reduce the energy available to the dipole so much that overall
propagation will be reduced?

Will the possibility of resonance at 10M in that eight feet induce RF
current in the outside of the sheathing in the rest of the feed line
on the other side of the choke? It is that current on the ouside of
the sheathing that the choke is supposed to reduce.

I neglected to mention that the eight feet of coax will be at around
25 degrees off vertical. Also, it will be around 30 degrees off
perpendicular to the vertical plane of the dipole. This means that
some RF from the dipole would be induced in it anyway -- even with the
choke right at the feedpoint.

I was wondering, if I use splitters to hook up multiple receiving antennas for a scanner, will I get good reception on the frequencies the antennas are designed for? I am particularly interested in having my Radio Shack mobile scanner antenna hooked up for general receive in the VHF band, as this seems to be the best portion of the spectrum for this antenna. I want to hook up an additional antenna for 800mhz by the use of a homemade spliter.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-14 18:31:45 UTC
From: 'Doc <w5lz@icok.net>
Message-ID: <3C90EC87.B1F9F724@icok.net>
Source record: 146705

JEEPMON,
A loop antenna becomes more efficient as the area inside
the loop becomes larger; circle, square, triangle. When you
just say a 'loop', in general it's understood to mean a full
wave length. If it's a 1/2 wave length, then it's usually
stated as a '1/2 wave loop' (1/2, 1/4, etc.).
Horizontal loops are usually omnidirectional, vertical
loops are usually bidirectional (depending on height). The
'pros + cons' of polarization are like most other antennas,
radiation in no particular direction, or in some particular
direction.
The input impedance of a full wave loop depends to a
large extent on the 'shape' and height above ground. The
more area inside the loop, the lower the input impedance.
As a very broad 'rule', it's input impedance is something
on the order of about 100 ohms. The less area inside the loop
the higher the iompedance, eg: a 1/2 wave folded dipole's
input is about 300 ohms. Feedline a full wave loop at a corner
gives it a 'vertical' polarization (sort of). Feeding it
on a side makes it horizontally polarized (sort of).
There are a number of ways to feed a loop with 50 ohm
coax. Any matching system will work (gamma, delta, etc),
or using a 'matching section' of 75 ohm coax, or ladder
line and a tuner/balun will work. Just depends on your
preference as to which one to use.
Most antennas will have a 'null', depending on it's
oreintation, etc. A vertiaclly mounted loop tends to
have a radiation pattern like a 1/2 wave dipole,
bidirectional (depending on height). The easiest way of
getting rid of the 'nulls' is to lower the antenna (not
the best way, but the easiest). I'm sure if you 'played'
with it long enough, changing the shape of the loop may
affect the 'nulls' (I don't think you'd get rid of them,
but you might get more of them).
The size of the conductor making up an antenna does
have an affect on it's performance, usually making it
broader banded to a point, and a few other things. Pipe
would work just fine. You'd have to experiment with the
lenght for tuning, but that shouldn't be a problem.
Laying an 'egg beater' on it's side will surely have
some affect, but I have no idea what (you rulled out my
best answer).
You might try a search using "full wave loop" and see
what you get. There has to be some information available.

good luck with your antenna project! Getting there is
half the fun, so enjoy the trip...
'Doc

Can anyone recommend where I can either buy, in the UK, (or get plans to make) a 2 element HB9CV antenna for 430MHz or 70cms?

Thanks

Yes, but it isn't the flimsy little stuff on *most* of them. Each finger is
1/4" wide and is extra
HD in order to withstand normal use. Now I won't say you *can't* break it,
but my exper-
ience has shown that, under normal use, it tends to last a long time. Plus,
if you break it within a year from purchase, I'll replace it free.

We have all seen these ads about the cellular "booster" antennas. you know, the dumb little stickers that are supposed to go between the battery and cell phone. The sellers claim . . . well you know what they claim unless you lead a very sheltered life.

These ads annoy me because, based on my assumption that there is no science that supports the claims made by the seller, they trick people into believing in magic disguised as science. Unfortunately, when the users discover that the "science" does not work, they learn to distrust real science as well.

Now I know very little about radio or electronics. But, A friend suggested that someone on this group might be able to help. I would like to be able to explain to people that these things are nothing more than so much snake oil. I have looked for and been unable to locate any authoritative source to which I can point the interested.

So, any takers? Specifically, I'm looking for an explanation that will work for the lay person or (Preferred) a net accessible article by an "authority" that will be recognized as such by a lay person.

Thank you for reading this far, and in advance for any thoughts you may have.

That's a pretty strong statement, and I disagree with it. My dipoles work fine without any connection to ground. The signals they radiate do reflect off the ground, which modifies the pattern, but this unavoidable situation isn't necessary to their operation in any way. There's a very large class of antennas tht, like a dipole, don't need a ground connection to function properly.

I almost hate to admit it, because I always thought they were "snake oil" too. But, a while back I was given one as a promotion, and thought I'd try it just for "grins"

I live in a remote area of the Mohave Desert, and my cellular coverage is very marginal at my QTH. Before using this "magic antenna" I had no signal strength readings on my cell phone when inside the house. I had to go outside and down the street about 500 feet to pick up 1 bar on the signal strength meter. With at least 1 bar, I can make and receive calls.

After I put the "magic antenna" on my cell phone (an Audiovox CDM-135), I found that I was getting 1-2 bars signal strength readings from inside my house, and I can now make and receive calls from inside my house. I know it shouldn't work, and I can't explain why it makes any difference, but it does.

It doesn't do what the ad claims - give you full strength reception where none existed before - but if you are on the very edge of a coverage area, it might help somewhat (it did for me).

True, but thats the price to pay for being low. My version with 4
radials was only about twice the wire of a dipole, but good for 2-4 S
units better signal to long haul stations both receive and transmit.
Pretty good payoff I think. My price to pay was having it at 36 ft.
But it was easy as my radiator is light and self supporting. MK

You can work dx thats for sure. I worked dx on 80m with a 35 ft high
dipole.
But I'd rather have the good vertical any day if I were really
serious. I don't work much dx on 80m. Thats my "regional" yik yak
band. I also remember W8JI talking about putting up high dipoles for
160m, and later considering them a waste of money compared to his
verticals. I think he also got the best reports on the verticals
overall. Haven't seen or heard him around much lately...He'd have to
comment on his 80m antennas...I'm more familiar with his 160m stuff.

> medium ground conductivity locations that will be likely true.

The way I look at it is you can't grill a steak with a bic lighter. If
you want "very good" performance out of verticals, you have to have
the radials or the height to avoid so many of them. There is no way

around this unless you live on the beach. This has been shown to be true time and time again. Look at the radials under Seviks <sp> short vertical he made that's in the handbooks. I doubt he would have wasted all that time and wire if it wasn't needed. Sure, a few less radials will work, but expect performance to be mediocre. Even with a full 1/4 wave antenna. I ran the same 32 ft vertical on the ground with at least 24 radials, maybe more, and the performance never even came close to the one up at 36 ft. You would think you were comparing a bugcatcher to a thin hamstick, it was that much difference. And like Cecil, the one on the ground rarely beat the dipole at 36 ft. The GP at 36 ft never once lost to the dipole at anything over 1500 miles. I can't think of a single time. Only on shorter hops up into the midwest at 800-1200, etc miles were they close, or the dipole winning. Of course, the dipole was usually the best in the daytime to high angle stuff. I'm sure the far field ground conditions will have an effect also, but if I were in a location that were marginal, I would go overkill on the radials to help make up for it. Instead of the four I used at 1/4 wave up, I might use eight. When I was working VK, and pacific regularly, I went up against all kinds of antennas 3 times a week. We had quite a group. The only ones that could beat me to VK were using bobtail curtains or yagis. The dipoles and loops lost almost every time. Maybe every time, but I'll give them a benefit of a doubt and say it may be possible they beat me once...:) I don't remember it though.. MK

Source record: 146622

I'm sure what Greg is asking, and the question that needs to be asked, is whether you compared the two antennas with EZNEC under the same conditions. The way to do this is to plot the pattern from one antenna and save the plot. Then plot the pattern from the other antenna, and superimpose the plot from the first antenna on it. This will cause them to be displayed at the same scale.

By default, EZNEC scales the pattern to put the highest field strength value, whatever it is, at the outside ring of the plot. (You can change this if you want by specifying a fixed outer ring value via the Plot menu 2D Outer Ring dB selection in the main window. This choice is saved with the description.) So if you retain the default behavior, one antenna can look better than another because of its pattern shape, but can in fact be inferior due to lower overall field strength. This is often the case when a vertical is being compared to a dipole.

In your original posting you tell how you've chosen one configuration over another on the basis of takeoff angle. As I've said several times before, FORGET ABOUT THE TAKEOFF ANGLE! Are you interested in the field strength at an elevation angle of 18 degrees? Then plot the dipole's pattern and look at the field strength in dBi at 18 degrees elevation. Then plot the vertical's pattern and look at its field strength in dBi at 18 degrees. Which is stronger? That's what counts. Likewise, judge your various elevated radial configurations using the same criteria -- not by what the takeoff angle is.

The first versions of ELNEC didn't report takeoff angle, because I felt that it was generally useless information, and was likely to mislead people. I was right. But customers asked for it. So I gave them what they want, not what they need.

If you find that the difference between a dipole and vertical is very different from what EZNEC predicts, it's possible that your estimate of effective ground conductivity is off. Remember, EZNEC assumes that the ground is homogeneous, so what it needs is a more-or-less average of the ground characteristics down to several skin depths. Although the estimate won't make much difference for a horizontally polarized antenna except at high elevation angles (it IS important for NVIS using horizontal antennas), it makes a large difference for vertically polarized waves. Note that the radiation off the end of a horizontal dipole or inverted vee is vertically polarized, so the ground characteristics can make a major difference to the pattern off the ends of these types of antennas.

A friend of mine bought one for his Motorola Startek. He reported considerable improvement in what had been dead zones. I've ordered one for mine.

I guess we should grant Val the 'One Humorous Truth' in his statement...

Without a 'ground reference' (as in a handy-dandy Small Blue Planet for example), how do you know if your vertical is really vertical ? Ha ha.

5138. INVERTED-L COMMENTS

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-15 02:28:26 UTC
From: ardujenski@aol.com
Message-ID: <20020314212826.09235.00001427@mb-cs.aol.com>
Source record: 146626

INVERTED-L: I did want to pass along in trying to maximize a portable antenna, after sevral months of basic calcs and operational tests found the INVERTED-L to be an excellent compromise antenna. With the BLACK WIDOW 20ft fishing pole (20ft by 20ft wire) I am able to work 80-10m with only a set of 12 --15 ft radilals. With the DK9SQ (33ft telescoping mast) and same radials am able to work 160 thru 10m. I have recently discovered that in playing with lengths of vertical and horizontal lengths to get all band impedance under 800 ohms (for auto tuners) the W3EDP 87ft wire run up a DK9SQ and then out horizontal will give low impedances and allow you to reduce the radial/counterpoise to a single 20ft wire and a ground stake.

The advantage I found is that it has two basic lobe patterns (high and low) associated with the horizontal and vertical portions. For close in operations the high lobe is dominent whree for more distant stations the lower lobe becomes dominant. This is like having an automatic switch between two antennas having two lobe patterns working for you.

This will at times make the antenna a little bit noisier in that it is receiving both low and high angle noise sources but have a second antenna (vertical) for comparison and sometimes a quieter reception.

The INVERTED-L eliminated the need for lossy loading coils and gives me a a good portable and homestation antenna. I do work from 100 watts down to just 1 watt operations and SSB and CW. During the last 160m contest I was able to work 28 states and Japan with about 50 watts. Feedline is 300 ohm twin lead.

The programs i used were from Reg G4FGQ. I have had a few calculations run for me on various arrangements on EZNEC and found the values to be very close. Thes programs are at :

http://www.btinternet.com/~g4fgq.regp/page3.html#S301"

Just thought I woudl share with the group and see if others have had similar experiences with the INVERTED-L

Yes, the inverted L works and works well!

There are of course much better antennas, but for the money and backyard space consumed, it simply can't be beat!

5141. Re: Distance from feedpoint to choke?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-15 04:11:42 UTC
From: Crazy George <munschNO@attglobal.net.SPAM>
Message-ID: <3c917842_3@news1.prserv.net>
Source record: 146629

The purpose of the choke is to decouple the feedline from the antenna so the feedline doesn't re-radiate. Usually radiation from the outside of the shield is considered undesirable. If you want undefined radiation from the feedline, then that is what to expect. Depends on your goal. Maybe you want a weaker signal in more directions than a pure dipole will give you. Remember all the signal radiated by the coax is subtracted from the dipole signal. Or added sometimes if the phase is favorable, but Murphy usually makes sure that is not the case.

Source record: 146630

Yep, that was the first thing I tried, as everything I have learned about antenna told me it couldn't work and was probably just a coincidence. So I stood in the exact same spot in the house where it was reading 1-2 bars on the signal strength meter with the "snake oil antenna". Without moving, I took the battery off, and peeled the "antenna" off. Stuck the battery back on and powered it back up. No signal strength indicated and I couldn't make a call. Stuck the "antenna" back on, and again had 1-2 bars signal strength, and could make and receive calls. Go figure... :>)

I tried it on my brother's Samsung cell phone at my QTH. It didn't work before or after on his phone, but he was using a different phone as well as cell carrier, and generally cannot make calls in my area, so this was not surprising. Like I said earlier, it won't produce a signal where none is present (like they say in their ad), but in marginal/fringe reception areas it seems to help a bit.

(I just hope I don't end up having nightmares about Fractenna's now ... :>)

> to be displayed at the same scale.

Yep, I did that for broadside to the dipole and off the end of the dipole.
The dipole beats the vertical broadside except for an insignificant
sliver. The vertical should beat the dipole by at least an S-unit off
the ends of the dipole for any arrival angle below 50 degrees but, in
practice, it doesn't seem to. I will post the graphs to my web page.

Isn't an elevation angle the angle at which the RF takes off? Aren't
there an infinite number of takeoff angles each associated with a
certain gain? Couldn't one have a chart of gain Vs take-off-angle for
take off angles of 5, 10, 15, 20, 25, ... degrees?

This radio is sold as a 10 meter rig but is easily (and most frequently)
modified for 11 meters. AM and FM only, no SSB. Comes stock with roger beep
and echo. Davemade amps are made for 11 meters. The man needs a dummy load.
not an antenna.

Here's what EZNEC sez about my 130ft dipole Vs my 33ft vertical
with 8 elevated radials. Even off the ends, the dipole beats
the vertical for waves arriving at 45 degrees or higher.

Well, what's wrong with this is that the non working EH is home-made
by one of us, there's no guarantie that it's made in the "right way".
I think it's made according to the docs, probably someone else might
think it's not well done.
However the one who built this home made EH lost somehow part of the
interest in working for a more accurate test on a EH made by its
inventors. Again, I'm not saying that we won't try more tests,
I'm saying that these tests aren't our life's main goal.

> Well, what's wrong with this is that the non working EH is home-made
> by one of us, there's no guarantie that it's made in the "right way".
> I think it's made according to the docs, probably someone else might
> think it's not well done.

Since I started this thread, please let me summarize my position on this
matter:

1) I don't understand the theory behind the EH antenna; the most possible
reason is that I am too stupid, but this is really not relevant here;
2) since I don't understant the theory, I would like to see the results of
PROPER measurements, before trying to spend some (or a lot of) time to
understand the theory;
3) Ted Hart was carrying out measurements under the supervision of
professional consultants; in principle, I would trust this approach;
4) the first test went wrong, and the blame was put on the "network"; this
was happening in October 2001.
5) early in January Stefano told us that some "amazing results" were going
to be published soon: we are now in mid March and we have heard nothing yet;
6) IF the EH antenna is able to work on 160 metres (and that's what we are
told), it MUST work on 1500 kHz as well.
- NOW:
I am NOT saying that the EH antenna is NOT working; I am saying that my
interest for this matter will "resuscitate" ONLY when I will see posted on
Ted Hart's Web site the results of the properly-made tests above, showing -
without any doubt - a behaviour that we cannot explain with the theories we
have at hand now.
A good contribution could come from Ted or Stefano, telling us WHEN those
"amazing" test results will be publised.
Till then, the EH antenna will be (for me) just another short dipole, and
all other bold statements will be just "noise". Period. And I don't think I
have been unfair with the EH antenna people.
(But, naturally, my opinion is only my opinion...)

73s,

Michele IZ2EAS

update...

This is getting interesting, but not very...
Received an email from KB9YTV stating his bank
has an copy of an money order cashed by me that
he will soon have in his possession.
Totally false...

Regards,
KA4NNN
Presley Travis

I've been thinking the same thing. Since the 3-meter antenna on the roof of my truck works FB a 20 meter (or less) 1/4 wave should work equally well on your metal roof provided all the sections are electrically bonded. Try it and let us all know how it does. I'm going to cover my whole house with tin next fall then reinstall the Butternut and see how it works.

I'm putting up an SWL antenna on the roof of a ten story office building.
The coax feed to the receiver will be 150' long. I'm concerned about
electrical interference the feed line may pick up. Eventually I will be
transmitting from this location (HF only). What coax type would you use?
Thanks for imput.

Ummmm, buy a 440MHz 1/4 mag mount and snip the whip? (Hell, why
bother, a 70 cm antenna should receive 800MHz real well....)

Ummm..... build one yourself?

Here are any number of sources for cheap mag mount bases or truck
mount bases with coax... Add a whip and you're all set... Seems like
about 10 or 15 minutes worth of work to fabricate one...

5154. QUESTIONS on the noise generator in the ARRL's noise bridge circuit

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-15 17:03:46 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0203150903.3ebf48e5@posting.google.com>
Source record: 146642
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.homebrew

I have some questions regarding the noise generator for the noise bridge circuit on page 27-25 in _The ARRL Antenna Book_ (layout at http://www.arrl.org/notes/hbk-templates/rxbridge.pdf). As you can see, the chief component of this is the NE555P chip (http://focus.ti.com/docs/prod/folders/print/ne555.html, http://www-s.ti.com/sc/ds/ne555.pdf).

The book says that this noise generator produces a 50% duty-cycle 1000-Hz square wave signal. This signal is applied to the cathode of the Zener diode and then sent on to the amplifier. So the NE555P chip produces the white noise and the Zener diode seems to be the mechanism on which this white noise is placed on a broadband RF carrier. I noticed that the port 4 (RESET) continuously receives 9V, presumably to ensure that the chip constantly resets and doesn't get stuck in one state (as some variation is needed to produce the pulses). Port 8, of course, needs 9V in order to keep the digital elements (flip-flop, BJT, and logic gates) running. Port 3, of course, is the output.

I wish the book described this circuit in more detail. My questions:
1. What does the 6800-ohm resistor between the VCC port and the DISCH port do? Does this influence the frequency of the white noise generator?
2. What is the purpose of the 6800 ohm resistor and two 1N914 diodes between the TRIG and DISCH ports? My guess is that it is part of a feedback network used to generate the square wave.
3. What is the purpose of the 1800 ohm resistor between port 3 and the D3 Zener diode?
4. How exactly does the D3 Zener diode modulate the output of the noise generator onto a broad range of RF frequencies?

YOu need to read up on how the 555 IC works. The two 6800 resistors along with the capacitor determin the frequency the circuit oscillates. One resistor is the on time and the other is the off time. The 555 will not give an exect square wave output of equal on and off times. The diodes are placed in the circuit to help make the times nearly the same.

The 1800 resistor limits the current to the zener diode which is acting as a noise generator and also isolates the circuit so the biggest part of the noise will go to the output to the transistor amplifiers and not be shunt to the power source. The zener does not modulate the noise output but it is the noise generator. The 555 timer output is turning the zener noise off and on at around a 1000 hz rate.

5156. Wire Antenna Materials your VIEWS?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-15 17:32:00 UTC
From: Deni <deni@gm3skn.fsnet.co.uk>
Message-ID: <a6tb6s$o5p$1@news5.svr.pol.co.uk>
Source record: 146644

What is the current informed opinion on wire antenna materials? Wire and insulators?
Solid copper versus stranded?
16 SWG copper. Covered or bare? If bare wire is used especially stranded does the inevitable corrosion on the copper strands cause any appreciable degradiation in perfomance?
PVC or similar covering insulaton invariably fails somewhere and then of course water enters and unseen corrosion takes place!
I wont even consider using any form of copperclad steel wires, bad experience with these!
I have constructed many wire antennas in the past with whatever I had available but right now I want to fit and forget the 'Ultimate low loss Doublet' using the best materials I can get, it also has to be rugged to survive weather and wind. It's to be around 132' top with open wire line feed, probably home brew line as I hate that 450 ohm copper clad steel windowline stuff!
Any comments or suggestions considered with much interest.

Hi Michele,

You and Francesco both present an openness to allowing the EH group to present their ideas and their data. Your tolerance is commendable in their short-fall of that same data. Forgive our correspondent's inclination to be down-beat about the qualities of this design. We here on rec.radio.amateur.antenna have often been immersed in "novel designs that confound the experts." Commonly, revealed through extensive writing, it has been shown that the "inventors" were often the ones most confounded with making even the most elementary measurements.

I would point out that in response to your statement:
>1) I don't understand the theory behind the EH antenna
would be acceptable in light of a general lack of understanding, but not in a specific understanding. This is the one great failure of these barn-yard philosophers who cannot express their theories except in profundities and abstractions. Such hopelessly dense explanations coming from home-spun savants exposes the vacuity of their ideas.

If you had earlier followed the great fractal antenna debate here, you would have seen all the hallmarks of fake science at work, complete with fractal theories and fractal electromagnetics to support contrived and pompous claims that were laid to rest through standard means.

>http://www.qsl.net/w5dxp/dipvsver.htm

Hi Cecil,

At the risk of playing specs-manship, I would point out that for
takeoff angles up to 10 degrees, you show the vertical is superior
(albeit in the most arguable fashion). And given that DX is
considered to be related to distance, the lower angles are the arbiter
of achieving that (as any sea side DXpedition seeks) goal.

However, reality does not confer automatic laurels to this particular
spec unless it supports it in propagation. Propagation may not allow
you to hit a distant spot with a take off angle of 5ï¿½ simply because
you may literally over shoot it. I would suggest those who enjoy
modeling antennas should also look into propagation modelers too to
observe just what payback is found in these issues.

I once posed a situation to VOACAP/WINCAP where I deliberately offered
it a truncated antenna file that launched at only one degree (not
literally 1ï¿½ above the horizon, more like at 10ï¿½ and ONLY 10ï¿½). When
that launched power hit the target, it was the size of a major state
in coverage. It would then only be an accident of layer height that
would allow me to hit a specific target.

On the other hand, pronouncements that the horizontal are better,
simply through the exhibition of generally great gain figures also
belies the reality of propagation. True, you may hit that distant
station better than the vertical, but were either of those two
actually aimed at it? Or was this simply the evidence of chance and
happenstance? The propagation modeler would expose just where ANY
design may shine and prevail over other designs (and equally expose
how little difference there is for the majority of power lost to
dormant receivers, ground, bedrock, or open sea).

I believe you have it the wrong way round..
The Diode generates the 'noise' and the 555 interrupts the 'noise'.
In reality, the 555 switches the power to the noise generating diode,
generating a signal that can be crudely called Amplitude Modulation
(I would call it a simple PCM without the 'code').
A carrier pulsed on a 1:1 on/off state will appear to be modulated if
it happens at an audible rate.
In switching at this 'rapid rate' harmonics will be generated..and
accuracy will be diminished.
I could be wrong.. I usually am

Hi OM,

Now that you performed this essential test, consider another.

Is this the property of the design? Replace it with a similar size
sheet of tin foil (with A/B testing as before, or perhaps A/B/C
testing, keeping the mystery device in the group).

For HF, RG-8 is probably sufficient, but I prefer LMR-400 (it is
better but costs more). Either will handle any reasonable power
levels on transmit, and will protect against received interference.
The difference is in the signal loss, but at HF it is slight.

I'd recommend LMR-400 just in case you decide to start doing some
VHF or UHF work.

Try a google search for "rg-8 lmr-400 loss" (leave out the quotes).

Hi Jason,

Your best and cheapest source of information about the characteristics
and application of the 555 come from the manufacturer. Motorola's old
handbooks and application notes are superb in this regard and go to
considerable extent for this chip alone.

The 555 establishes the dominant low frequency characteristic as the pulse edges are the compelling feature of harmonic generation. The Zener is the source of MF/HF/VHF noise. If you want to focus on anything, it should be the Zener. As an experiment, you could remove the Zener and couple this pulse through a transformer (about 1:10 or greater) and fire an NE-2 bulb which will be harmonic rich too (gas tubes are very noisy). I don't imagine that it would show any greater noise field however, unless you contrive to dump more power through the tube (or Zener for that matter, in that regard, try biasing it into greater or less conduction).

Keep in mind that the purpose of a white noise generator is to spread the AVAILABLE power EVENLY across the spectrum. The same power applied to any noise generator can only replicate this characteristic (unless the substitute is not equally suited for the purpose of noise generation). Again, focus on both the power applied, and the noise generation mechanism (there are many candidates). A mercury wetted reed relay feeding an Ampere to a one ohm resistor will overload you with harmonics of the reed's drive frequency. The principle benefit of such a suggestion lies in the exceptionally fast rise and fall time (sub nanosecond) and power handling capability. I won't go into the environmental risk and the possibility of this device becoming a controlled substance by the way.

In the present case, the philosophers * did * express themselves in a rather crystal-clear fashion: trouble is, that what they expressed as nearly no significance, and so is tantamount to nihil, for anybody knowing the 101 of field theory....
Really, imho, for the moment there is no theory behind EH and, unless a serious set of measures, conducted like scientists use to make it, is disclosed, chances that someone confront the difficulties of theoretical analysis are very few...
:-)

The 555 produces a chopped DC supply to the zener (actually, avalanche)
diode. The diode produces the broadband RF noise.

For information on how the 555 works, take a look at a
practically-oriented electronics text such as 'The Art of Electronics'
by Horowitz and Hill.

>3. What is the purpose of the 1800 ohm resistor between port 3 and
>the D3 Zener diode?

To set the current through the diode, and also to act as an RF 'choke'.

>4. How exactly does the D3 Zener diode modulate the output of the
>noise generator onto a broad range of RF frequencies?
>
D3 *is* the broadband noise generator.

At my QTH the two extra S-units of noise on the vertical needs to
be taken into account. In any case, I was expecting the vertical
to perform better than the dipole off the ends of the dipole.
In actual practice, that is rarely the case. The dipole is a
pretty good NVIS antenna off the ends. I cannot seem to find
a use for the vertical. Phasing two verticals to get an additional
3dB wouldn't even overcome the 2 S-units of additional noise.

Source record: 146653

I use a mixture of horizontal (dipole, quad) and vertical (ground mounted) antennas. The dipole is up only 20' and the quad is centered at 45'. I find that each has its place. As would be expected, the quad is usually better (on 20 - 10 meters), but not always. I can easily switch antennas without retuning, and it is interesting to watch polarization change over relatively short periods of time. Also, sometimes the vertical seems to hit a particular location better than the quad or dipole.

The quad is usually quieter (background noise) than the verticals. However, if my verticals were *always* two S units (assume 10 db) noiser, I would start looking for other problems.

I have the space (1 acre) for several antennas, and I enjoy having a selection. In my mind, the general question "which is better" is not a meaningful question.

Steve,
Just depends on how much you want to spend. RG-213 would
be a good 'average' choice. Not a whole lot of loss in 150 feet
and available almost anywhere. '9913' would be nice, but a real
pain to run, stiff and heavy. I don't have any experience with
the 'LMR' series of cable, but it shouldn't be any worse than
most. Good luck.
'Doc

Deni,
Despite your bad experience with it, the copper clad
steel wire is your 'best bet'. If reasonable care is
taken, it should last as long as you do.
Stranded wire, depending on the air polutants in your
area, tends to get 'noisy' after a while. Insulated stranded
wire takes longer to get 'noisy', but will eventually too.

The "best" coax is 2" outer conductor diameter line, the outer conductor being formed from 6 longitudinal annealed copper or soft aluminium overlapping tapes, each tape having a thickness of 0.015".

The inner conductor being 0.5" diameter, solid copper conductor. With an extruded solid polyethylene insulant.

Forget about such things as SWR and dB per 100 feet and call CQ.

Solid copper, enamel-insulated, 16 or 14 gauge wire lasts for years and years. Try some. Its cheap enough. Obtain it in scrap reel lengths from electric motor and small power transformer repair works. Scrape off the enamel and it solders very nicely too.

Source record: 146661

The poster was from the Shetland Islands. I don't know how close he might be to the ocean, but I had one experience at my parents' house about 2 blocks from the Pacific on the Oregon coast. At that location, the wind in nearly always from the west (the ocean), and in contrast to its name, the Pacific is very seldom calm at that latitude. So good-sized waves are constantly breaking against the rocky shore, providing a steady source of atomized salt water. This is blown inland by the prevailing wind. The result is that the air constantly contains microscopic droplets of salt water. Here where I live about 100 km inland, the climate is very rainy but lacks the salt spray. I've had bare copper wires up for 20 years with nothing but a little oxide formation. But I once set up an antenna for a shortwave receiver at my parents' house at the coast, stringing some #14 or so stranded copper wire under the eaves of their house. In less than a year, the wire had turned completely into blue-green powder and was gone. I don't mean corroded, I mean gone. In that climate, even aluminum corrodes, but any copper that the air can contact is gone very quickly. So if the poster's climate is anything like that, then the only solutions I can see are stainless steel wire (which might be noticeably lossy), or copper wire with a very, very stout coating. If I were putting up an antenna in a climate like that, I think I'd try using TV twinlead or ladder line, with the conductors tied in parallel. The polyethylene coating is thick and rugged, and conforms to the wire very well, which should minimize moisture leakage at the ends. I'd use RTV or a similar compound liberally at the ends and wherever bare copper would otherwise be exposed. (I don't want to start another long thread about the alleged corrosive properties of RTV. I've used a number of brands of acetic-acid smelling stuff for purposes like this on many occasions without any corrosion problems. But suit yourself and use the less stinky stuff if you want, and if you can find it.) I don't, however, have any direct experience with constructing antennas intended to last a long time in a maritime climate. Maybe some people with experience on seagoing boats will share their knowledge. I also don't know if the poster's climate is like the one I described. If not, then just about any kind of copper wire would probably do. But just because "I've used bare copper for years without any problem" doesn't mean that everyone can get away with it.

I've had very good luck with Copperweld (a brand) of copper-clad steel wire. It has a very substantial copper content (perhaps 30% or so of the total thickness). Don't confuse it with something like copper plated electric fence wire, which has a very thin plated coating. Copperweld is as strong as steel and as good a conductor at RF as copper. It is a nuisance to work with because it's springy. But once up, it'll never

come down. Of course, it's bare copper on the outside, so isn't any more suitable for a maritime climate than solid copper.

Hi Roy!
Great to read of your views on wire Antenna materials. I am indeed on the shores of the mighty Atlantic on the west coast with the great North Sea to my east so the crumbling green copper stuff is quite familiar to me.
The winds also demand great respect and a certain amount of 'over engineering' pays off when it comes to antennas!
I am most interested to hear of all views on this fascinating subject.

A spark of life on a wire from heaven!

If it picks up interference, it will most likely be because you haven't properly de-coupled it from your antenna, and it's feeding signals up the outside of the line to where the antenna connects to it, and then down inside the line. It should not matter significantly whether you use extra-super-special shielding or standard RG-213 single-braid cable. (Though don't bundle it tightly with power wiring! That's asking for trouble no matter what else you do.)

Probably a bigger concern is the length. If you use "small" cable like RG-58-size, you'll end up with around 4dB of loss at 30MHz, assuming low SWR. I'd go with larger cable...RG-213 size drops the corresponding loss to under 2dB (for a line with low SWR, anyway), and some of the fancier lines that size or a bit larger drop it further. I'd personally go for the reduction from 4dB to 2dB, and say that anything lower than that wasn't worth my effort, at least for HF. If there's a chance you'd use it for work at 146MHz or 440MHz, that's a whole 'nuther story.

Another consideration is what environment it's exposed to. If it's exposed to UV (sunlight), be sure to use a line that will stand up to it. It may be worth putting a conduit around it just to protect it where it's in the open, as much as you reasonably can. And if you run it in an air duct, be sure it's rated for that--"plenum rated".

I'm sure others will have more specific recommendations about brands and stock numbers....

Cheers,
Tom

Reg:
You don't think big enough. A number of years ago one of the nearby TV broadcast stations discovered they had a mis-manufactured feed line, and replaced it with new. Sold the old line for the price of scrap copper. Still relatively expensive, but it is 1200 feet of 6" outer diameter air insulated (erratically spaced teflon posts to avoid resonance) with a copper pipe center conductor of about 1.5". I could only afford 4 joints of it. Not very flexible, though, I have to admit.

To supplement what Roy has said:
I have experience with Cu wire antennas in salt spray. Not having had any choices, I coated the wire with RTV (ironically, it was black RTV) where I could. Where I did not coat, the wire was black in a couple of days. When the project was over, the wire antenna was taken down. Latter examination found that the wire under the RTV looked like newly minted pennies. The project did not last long enough to learn how long it takes for the spray to get through the rubber. The hand coated wire is not good looking!
I too have not seen corrosive properties of the RTV that I have used. Yes, it had an acidic smell.
To last on the coast of GM land, one should be able to find heavily coated wire. Wire that is intended for high voltage applications. 73

It makes me wonder, then, what the communications guys use for dipoles on the big ocean liners, military ships, etectera that are constantly exposed to marine atmospherics. Might be something you could research on Google. (I'm currently reading "The French Atlantic Affair," about a ham who sneaks his transceiver aboad an ocean liner, and strings up a 20 meter dipole. Fascinating stuff.)

I can be a little more specific about Reg's comments. I don't know what the UK equivalent is, but either "Formvar(TM)" insulation, or nylon overcoated enamel insulation are extremely resistant to abrasion, and therefore will last a long time before the weather gets to the copper.

On the other hand, I have a couple of observations: The Statue of Liberty wears a copper coat. I understand from reading in corrosion publications that it is not eroding, and the thickness does not decrease. Why not?

Then, in 1990, I personally examined AWG 10 bare hard drawn copper wire which was installed in 1969 within sight of the Atlantic Ocean on the island of Puerto Rico as a backscreen for a DF set. Approximately 100 feet long pieces. Brown in color, and as close as we could measure with a standard micrometer, the same diameter as it started out. No general green corrosion, some spots. The ground mat was AWG 10 Copperweld (TM). Installed at the same time. Rust showing on cut ends, but as far as could be measured in the lab on pieces we extracted, still the same coating thickness as when manufactured. When the site was destroyed by hurricane Georges in 1999(?) (didn't look up my records), what was left of the wires looked the same as they had in 1990. Failure was poorly welded bolts holding the upper boards to the support poles, which were supposed to be single piece bolts anyway. Installer cheated and got away with it for 30 years.

I have seen stranded copper wire turn to green dust as Roy reports, but I always wonder if it started out as an alloy for flexibility?

5182. Switchable amplifiers WITHOUT stray capacitance/inductance

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-16 04:58:40 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0203152058.d5a6e84@posting.google.com>

I would like to build a modified version of the SWR noise bridge shown on page 27-25 of _The ARRL Antenna Book_. The schematic is available at http://www.qsl.net/wq1rp/noisebrg.htm, as the New England QRP group sells a kit.

One of the modifications I would like to make is an extra RF amplifier. More forward power means more reflected power given the same SWR. I want the noise from the noise bridge to be stronger relative to RF picked up by the antenna, because noise spikes or strong signals can foil my attempts to minimize the SWR on 80m and 40m.

At the same time, I would like this extra power to be OPTIONAL so that I don't have to waste the battery. This requires use of a switch.

However, I understand that the variable resistor and capacitor in the original design of this circuit are sources of stray capacitance and inductance. Would using a switch have a similar effect? If so, what would it take to minimize this?

In regards to exposed copper wire. What if you sealed the wire with a couple of coats of polyurathane. Even in salty air I think that the poly would protect it.

Im new to the Amateur radio hobby, and I know nothing about antennas. But I do know about polyurathane.

You may want to look at the ground independent Force 12 shortened half wave
verticals. they don't require radials.

There are, unfortunately, two meanings of "takeoff angle". One is the elevation angle, as you say here. The other is as reported by EZNEC, and as you used it in your original posting, the elevation angle at which the pattern is maximum. When I say to ignore the takeoff angle, I mean to ignore the elevation angle at which the pattern is maximum.

Hi Jason,

There are many issues with this design, one of which is that it is a fixed bridge and may not meet your expectations (the bridge is balanced against the 100 Ohm resistor on the "unknown" port). In other words, the layout is not conducive to balancing the arms of the bridge, but rather seeking the balance of what is applied and changing it. It is presumed that the Hi-Z of the "unknown" presents only the 100 Ohm to balance against R1 and C1 is adjusted to compensate for stray capacitance at the "unknown" port (you will never eliminate strays, it is more meaningful to know how to balance them).

Your question about the switch should be immaterial to the operation of the bridge as the source sees only the receiver as a load with a balanced load of R1-C1 and "unknown" in parallel. That is, stray capacitance to ground may affect HF/VHF performance (sensitivity) but not accuracy of balance aside from severe imbalances due to stray coupling to ground or in the coupling from source to R1-C1 and the "unknown" port. In this last regard, the principal culprit is found in the bridge's transformer and the very near connections shown by the layout (not a good idea). This is a rather fine point, one where accuracy is jeopardized, but the authors treat this project as a low accuracy (but adequate) device. Don't project problems of low noise amplitude until you build it.

It is a good begining, but the authors' conjecture that phase angle can be found is dreaming in technicolor with surround sound.

That's a really good point about the Statue of Liberty and corrosion. A good brief description of copper's reaction to the environment can be found at http://w3.gsa.gov/web/p/hptp.nsf/035c614b995c0406852565d1006211b3/f0c205eec8a1107a852565c50054b3f8?OpenDocument.
(You might have to paste this URL back together.)

The Statue of Liberty is covered with sheets of pounded copper, which might not be too pure. But the link above indicates that even pure copper should develop a relatively nonporous coating preventing further corrosion. How about this for a theory -- the wire flexes in the wind, constantly cracking the patina and letting salt water penetrate deeper?

5189. Verticals over sloping terrain?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-16 09:31:38 UTC
From: k3bu@aol.com
Message-ID: <20020316043138.06415.00002517@mb-fi.aol.com>
Source record: 146576

I have been with verticals at the ocean front and seen the benefits.

I have this question about the verticals installed on the sloping terrain, like hillside. I wonder what the sloping hill would do to the vertical antenna performance.
What does it do to far field (Brewster) and radiation pattern at low angles?
Any practical experiences, measurements or clues from the terrain modeling out there?

Yuri, K3BU

What you need is Brian Beezley's TA (Terrain Analysis) program. It takes as its input a free-space elevation pattern from EZNEC or from one of Brian's programs, lets you make the ground any shape you want, and tells you what the resulting pattern looks like. I've used it for several years to evaluate Field Day sites, and feel it's reasonably accurate. It's amazing how much field strength you can gain by picking the right location and placing your antenna at the best spot for the location. I think you can contact Brian at k6sti@n2.net.

I think the layer of oxidation inhibits (not prevents) further
corrosion.

Here at my QTH, (about 1000' from the sea) copper is the one metal that
DOES last. Granted I don't have regular damp salt spray and its very
dry here.

I recall the electrical system in one of the small islands here. They
insisted on staying with copper conductors, even for house service
wires, until just a few years ago when pricing and outside consultants
(sri Geo) finally dragged them kicking and sceaming into the ACSR world.

For shorter antennas say 80m and up. I've used the Low voltage cable used by
accent lighting companies , It looks like heavy duty zip cord but has a much
tuffer jacket. If you weather proof all the connections it seems to hold up
very well in a salt water enviroment. Drawback is it's kind of expensive.
and I don't know if it's available in the U.K.

I once had a 40m vertical with plenty of radials on a hillside
overlooking the sea. It was about 80' in elevation. It performed
superbly for long haul DX in the direction of the slope but was very
deaf on the backside. I imagine the hill completely blocked it.

Thanks Roy, I'll stick with the coax then. Of course, my ATU which has the 300ohm output must have a matching transformer to convert 50ohm into 300ohm anyway so there is no difference really.

Thanks,

John

This might be a little off topic, but I have taken the broadband noise circuit from one of the other ARRL handbooks, and added enough gain after the diode. The result is a noise generator that will put out 0dBm from 10KHz to 1.3GHz, with a flat output across this range. I would be glad to share the circuit, along with board layouts to interested parties. What I use this circuit for is characterizing RF filters, along with a spectrum analyzer.

Jitendra,

Thank you for your answer. I need just a practical approach, depending
on frequency or even time domain charactristics. It is not important
if it is automatic or not, but I need to discover the modulation type
of a given signal. At present I don't have access to the book but I
have the paper. Although I have not read it completely but I think it
is not so practical. Any way, thank you very much for your help.

Hi Deni,
Copper is ok
But it does have its faults.
An alternative:
Go to a yacht riggers. Get 3mm stainless riging wire.
Most military antennas are made from this stuff now.
It is not over expensive. (more expensive than single strand copper)
You can get stainless steel crimp connectors for it.
Use stainless thimbles etc.
It will last forever. you can tension it very tight if you need to support
feed wire at the center of a dipole.
Regards Peter, G0LRP

You really need to understand how the noise bridge works, before you
start modifying it.

You have a bridge, consisting of T1, C1/C2, and R1. Your receiver is
the level indicator. You have an unknown impedance, which would often
be the antenna. And you need a signal source.

You can read up on bridges, in books like the ARRL Handbook. The
basics is the same as a resistive bridge, though in the case of the noise
bridge you are dealing with more complex components.

But the basic idea is that by adjusting one leg of the bridge, you balance
it with the leg with the unknown impedance. When the level indicator
is at it's mimimum, you have balance. Since you can calibrate the
components in the bridge, then you can read from them the value of the
unknown impedance.

I passed over the signal source, deliberately. You want a signal
at the frequency where you are operating. If you go looking, you will

find this sort of bridge with the signal source being a low power transmitter, or even the station transmitter. The problem with this is that you need to retune it as you move in frequency; this may mean a bandswitching unit if the signal source is built into the bridge, and unless you put a lot of effort into it, you'll have to keep retuning things in order to keep the signal in the passband of the receiver.

So at one point, someone came up with the idea of a white noise source as the signal source. It puts out more or less constant level signal throughout a large slice of spectrum, so you don't need to retune the signal source.

As for the level indicator, I'm sure if you looked, you'd find similar bridges that used things other than the station receiver. But the usual ham does have a receiver, so it saves costs. Otherwise, you'd need to build up some sort of sensitive level indicator.

Take a look at the 2001 ARRL Handbook, there's a different noise bridge in there. The circuit is probably in other recent editions. You will find the same basic circuit, but with a different implementation. The bridge portion is the same. But it uses an IC to amplify the noise generator, which is a zener diode like the one in the Antenna book. The significant difference is that the noise source is not modulated. (In one of these threads of yours, someone suggested modulating the noise source to help in finding the null. That's what the 555 in the Antenna book schematic is doing.)

And a noise bridge has nothing to do with adjusting SWR. It's a piece of test equipment for measuring the impedance of the antenna (or some other device). The variable R and C are your readouts. The only thing you can adjust to improve things is by fiddling with the actual antenna.

Phosphor Bronze is commonly used for non-insulated naval antennas due to its corrosion resistance. The only reason for insulating it is to protect against precipitation static, which is not really needed if only used for transmitting.

More details can be found in "Shipboard Antennas" by Presont E. Law Jr.. published by Artech House Inc. (sorry I don't have the ISBN). And, I am sure there are other publications on the subject of antenna materials in corrosive atmospheres.

NOTE: My version of the noise bridge will NOT have the variable resistor and capacitor that the original has. I will operate it by hooking it up, adjusting the antenna for minimum SWR for resonance, and then making any additional adjustments (if necessary) with my tuner.

In other words, the purpose of my noise bridge is to tune the antenna WITHOUT using the transmitter. My noise bridge will be more like the MFJ-212 Matchmaker (http://www.mfjenterprises.com/products.php?prodid=MFJ-212), which does not have the resistance and reactance dials.

5204. Butternut HF6V SHOCKING question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-16 19:33:48 UTC
From: Ken Linder <radstream@lvcm.com>
Message-ID: <u977h8atpo145a@corp.supernews.com>
Source record: 146592

Well, of all days, it is actually snowing and raining today in the foothills of Las Vegas. 'Great,' I think to my self. No yard work, can't wash the car, wife is playing bingo and daughter is at a friend's house. Perfect day for ham radio. The night before, I had plugged my antenna coax into a grounding block because of the possibility of thunderstorms. When I unplugged it from the block, electricity arced over to it. I quickly released the plug & dropped it on the table! I could hear the thing sizzling with electricity. I carefully picked it up by the coax so as not to be jolted and brought it closer to the grounding block. At about one inch away from the block, electricity was visibly arcing over from the center connector to ground. After about 15 minutes it stopped, then started again. I decided this be a better computer day than ham day! I am glad I didn't have it plugged in to my radio!

Has anyone else experienced this? Any idea what this might be from? It is an older HF6V with a very new CPK (Capacitive Counterpoise Kit). I operated this antenna for years with radials and never had this happen, although I do know that in that configuration the entire system operates at DC ground. With the CPK, neither the antenna or CPK operate at ground, their voltage floats... I guess that is partially how it tunes the antenna without radials.

Comments? Thoughts?? Have I found a new power source I could sell??? :-)

5205. Stupid question on ferrite antennas

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-16 19:48:04 UTC
From: stephendeese@hotmail.com
Message-ID: <25cad608.0203161148.1cd64b06@posting.google.com>
Source record: 146593

I have been wanting to build a 60Khz ferrite antenna (WWVB) but have very little experience on the RF side of electronics.

I am assuming that ferrite antennas are simply a LC circuit, with very high Q and tuned for 60khz (in this case). I took apart a Radio Shack atmoic clock and examined the antenna. My question is this.... How can I build a better antenna?

I suppose that there could be many combinations of L and C that would give you the same Q at 60khz. Therefore, does the antenna's ouput become stronger with the use of larger values (i.e. large ferrite rod, L and C)?

I have physical room in my application for the antenna to be 2 - 3 x larger than the Radio Shack (approx. 2 in long) antenna.

Any suggestions? And good books that cover this kind of thing (I am currently reading RF Circuit Design by Chirst Bowick.... which looks good)?

Again, thanks for ANY help on this. I realize that this is a very ingnorant question.

Thanks and May God richly bless you in every way (in Chirst)
Stephen

>Yuri, K3BU

Hi Yuri,

The Brewster angle is unaffected by such considerations. This is a characteristic of the far ground seen from the radiator at shallow, depressed angles (from the current maxima). Having a hilltop vantage only forces that angle's strike point out to a more distant geography; it is the soil (or sea water) characteristic at THAT point that will determine what the Brewster angle is and if you will encounter absorption or reflection.

Let's put it another way. If you were to presume a uniform soil characteristic; then that characteristic's Z in relation to the Z of free space dictates at what angle (the Brewster angle) where the critical changeover from absorption to reflection takes place. If you raise the origin of the ray (the straight line from the current maxima to the strike point at ground), you extend where the strike point occurs. If the ground characteristic imposes a Brewster angle of 5ï¿½ (we should all be so lucky); then a 5ï¿½ depression will strike ground further away if the origin of the ray is raised.

Of course, this can be used to advantage if you have the flexibility in adjusting the current maxima's height (through either the selection of quarterwave or halfwave or 5/8 radiator OR simply raising the radiator). The peak of hill would be suitable, if its slope falls away faster than that same 5ï¿½ depression. One side benefit is that local ground at a peak or ridge pulls lossy ground away from the near fields; hence less loss. This, too, affects the low angle of the lobe, and all angles for that matter.

I've assembled a shorthand of various conditions to illustrate:

strike point terrain DC Zc Brewster angle

heavily wooded land 2 266 40ï¿½
poor soil 4 190 25ï¿½
good soil 30 65 9ï¿½
undrained soil 80 40 6ï¿½
lake/sea 80 10-20 1.5ï¿½-5ï¿½

The principal gain of sea-side conditions is in the enormous impedance mismatch between it and free space (a SWR of nearly 40:1) that all but guarantees total reflection (until that critical angle is achieved, of course - which abnegates the mismatch). The discussion above is derived from material in Bailey's "TV and Other Receiving Antennas" and various other sources for some numbers.

>k5qwg

Hi Bob,

Having been a teacher to Navy Electronics techs in ET "A" school (A3N
branch, Communications) I would offer there are few dipoles aboard
ships (aside from ship-to-ship VHF/UHF). All radiating surfaces were
painted (this conforms to the service maxim that if it moves, salute
it; if it does not move, pick it up; if it weighs too much, paint it).

However, this is not true historically. On my wall is the photograph
of a line of pre WWII battleships entering Puget Sound. The photo was
taken from the signal bridge or fire control director looking back
over the aft gun turrets. In this photo are seen the far points of
two large for/aft dipoles each developed from 6 wires in a cage
configuration. There is little advantage to horizontal antennas in a
mobile configuration during war - in fact it would be quite a
detriment (the VHF/UHF dipoles were mounted vertically).

Hi Jason,

You WILL NOT have R1-C1? It will not be a bridge then. These are (in
order) the reference and compensation for stray capacitance seen at
the "unknown" port; without them, you will never see a balance. Such
sweeping design changes will devastate the circuit, much less
eliminate any chance of accuracy (even for amateur work).

R1-C1 are not user controls in the first place, so you have missed the
intent of the previously suggested design. In other words, the two
designs you've offered are much more alike than dissimilar.

As a matter of practical design consideration, can you present us with
a schematic of the stripped down design of either bridge circuit? It
should reveal ONLY the principal components (black boxes for source
and detector are suitable here for simplicity's sake). Your
discussion through several threads suggests you are not familiar with
bridge topography and this ï¿½tude would be beneficial (and necessary).

Source record: 146599

The ferrite rod antenna is the most inefficient of all small antennas.

The larger its volume the less inefficient it becomes.

Don't worry about Q. What you are really interest in is extracting the maximum amout of RF power from the 'ether' and injecting it into the receiver's first transistor with minimum amount of loss in the antenna itself.

The basic ferrite antenna is just a coil wound on the rod with a tuning capacitor in parallel with it. It is best not directly connected to anything else.

There is another coil with relatively very few turns wound on top of or alongside the main coil. This is a coupling coil which couples the main coil to the first transistor. The two coils behave as an impedance-matching step-down transformer.

For a single frequency receiver such as 60 KHz just wind a lot of turns, a few hundred?, on the insulated rod and then find a siutable fixed value of tuning capacitor. Use a junked rod from a medium or longwave transistor radio. You could possibly retain the same winding with a much larger fixed tuning capacitance.

For starters, on the coupling coil try 1/20th of the turns on the main coil and connect it to the base of the first transistor.

To minimise loss in the wire of the main coil us Litz wire. Litz consists of many specially woven very fine wires, separately insulated, all connected in parallel. But Litz is not essential.

If you can't find much to read about ferrite antennas in the books then that's because they are so simple there's hardly anything to write about.

A note on receiving efficiency and antenna size - For an antenna to be very efficient, say greater than 70 or 80 percent, its largest dimension must very roughly be at least 1/3 of the wavelength of the frquency it is intended to receive.

The wavelength of 60 KHz is 5 kilometres or 3 miles.

A 6-inch ferrite rod is 1/32,000 ths of a wavelength so don't expect very much from it unless the transmitter is very high power. A 3-feet square multi-turn loop (no ferrite) is a much better proposition for long distance long-wave reception.

With a 200-feet inverted-L wire antenna and a good ground you will be getting somewhere.

Make the receiver first.

Have fun !

Put 'hb9cv uk' into Google.
It gives many useful links.

> and giving me the opportunity to learn something new.

I had always heard that elevating the radials to 1/2WL would drastically
improve the low angle radiation. According to that model, tain't so.
With the radials at 20ft, the maximum gain is 0.13dB at 18 degrees.
With the radials at 60ft, the low angle gain is -0.52dB at 13 degrees.
At 60 ft, the maximum gain is 1.83 at 47 degrees. The low angle radiation
with the radials at 1/2WL is 0.65dB less than with the radials at 1/6WL.
That's why I chose 20ft for the height of my radials.

Of course. It's simple static electricity. When I lived in the Phoenix
area, windstorms caused my G5RV coax connector to arc once every few
seconds until I woke up and thought it might set my carpet on fire. I
hear snow can cause the same thing but I don't have much experience
with snow.

Date: 2002-03-16 23:01:14 UTC
From: rons533@dejazzd.com
Message-ID: <3C93CE73.5994@dejazzd.com>
Source record: 146604

I just installed the TGM MQ-2 6 Band Hybrid Quad mini beam antenna with the Centaur 1:1 balun. The antenna seems to be working fine as far as signal strength is concerned over my vertical but I don't notice much difference in F/B Ratio and not much difference when I put the side to a station. SWR is right on for all bands as per instructions. I suspect it may be the balun. Should the problem be worse without the balun? If you are using no balun or another brand of 1:1 balun I would be interested in your observations and hearing what you see in F/B and side lobe? Don't get me wrong, I like the antenna very much but I want to improve upon what I have.

Andy,
The AH-3 and AH-4 antenna tuners can be used with any radio. The AH-4 will tune ant time it detects a high SWR. Look at the mods for the Icom 706 and somewhere it will explain the plug on the back of the rig and the way to make a tuner simulator plug.

An interface would be a simple power switch to the tuner.

Be sure any rig you connect has less than 10 Watts output when the tuner is tuning!

Sorry I do not have time to get you the info, but I am going out of town tomorrow, be back next weekend!

Hi Ron,
Unless the balun is not functioning as a balun and allowing p/u from the coax shield, it cannot affect the antenna's pattern- just the match.

Thanks Roy,
I have his AO, I was going to find out about TA, if it would apply to verticals over real and sloping ground.
I am in the process of populating abt 140 acres with antennas, we have a ridge sloping south, so I am curious how would fixed vertical arrays perform on the slopes. Attenuation in the back is welcome. Just curious how close, if possible at all, it is to get to the sea side effects.
I will have an option to utilize the terrain to enhance antenna performance, so it would be interesting to play with some vertical curtains, etc.
If TA can answer some of these questions, I will go for it.

That's great, we need ridge like that in the middle of the ocean. But now that I am looking at inland QTH I wonder how much benefit will it have to be on sloping hill. I guess I will try TA and plant some stuff, so I don't have to claim the tower or shear my fingers with crankup :-)

I don't find the front to back very dramatic, especially on 20 meters. Seems better on the higher bands, but that is to be expected with the shortened design. The front to side should be plenty noticable though. How high are you mounted? Maybe you are to close to the ground?

Hi Stephen,
there is a book by the late Doug Demaw entitled
Ferromagnetic - Core Design and Application Handbook that you
may still be able to get from the ARRL. My copy was published by
the MFJ Publishing Co., Inc. of Starkville MS 39759. You might want
to contact them. You might also want to get the AMIDON, INC. book
from Amidon or Bytemark if it's still available. These books will help
you with the specifics. Try the Radio Shack antenna. If it works you
won't need anything else.

Tom Donaly KA6RUH

(P.S. Don't trust anyone who tells you you can cut a ferrite antenna
to size with a hack saw.)

My QTH was in the middle of the ocean. We've made contacts with you
(VP2EXX, etc). Truly, the norm was 20db+ pileups with JAs in the
mornings...even running QRP. Often, working by call areas wasn't
sufficient...I often went A, B, C (a la Father Moran) with the JAs.
Switching to a dipole resulted into 'barely audible'.
All that being said, the vertical was no good in any other direction.
It was one of those lucky combinations that worked.

When I am not using it, I move the antenna coax to a grounding block, but acording to the instructions for the CPK, no part of the antenna is supposed to be run to DC ground. Of course, a standard radial set-up with a HF6V would have the whole thing grounded to DC. Makes me a little worried operating with it now... :-/

When I lived in Denver, my coax connector would often arc when a thunderstorm was approaching. 30-foot high antennas would audibly fizzle and crackle. I recall once having the center conductor of the feedline to my 8 foot mobile whip arc through the car's floor insulation to the floorboard. It also could be heard sizzling and crackling. Static would arc across a tuner's wide-spaced variable capacitor on Field Day. It's common in some parts of the country. Here in Oregon's Willamette valley, we might have a couple of lightning bolts within sight or hearing distance in a year, and never that kind of static discharge.

I am only 30' off the ground. I was thinking that this may be the
problem but it is as high as I can go.
Even with this minor problem the antenna is still great.

Sounds like you're trying to build a return-loss bridge. Works good with a spec-an with a TG. Zach Lau did a couple of articles for QEX a couple of years ago describing the use and construction.

It happens frequently here in Calgary during windy periods.
A neighbour was
in my shack one evening and I was swinging the bands
showing him what
kind of activity was going on when I started getting arcs
across the caps in
my tuner (no cabinet cover). You could actually see a glow
develop just before
the arc. It scared him so bad, and despite my explanations,
he took off and it
was quite a while before I could get him down in the shack
again.

Hey, Richard...

Admittedly, I don't know beans about maritime radio, but I notice in my AES
catalog there are two general types of marine radios being sold -- 25 watt VHF
transceivers, and 150 watt SSB transceivers operating from about 2-23 mhz. I'm
assuming the latter type typically use dipoles, random wires or perhaps some
kind of vertical whip.

Not on the ones I've modeled. A 1/2 wave up and the pattern "shows" to
go upwards quite a bit. This type pattern seems to last up until you
get well over a wavelength high.
> With the radials at 20ft, the maximum gain is 0.13dB at 18 degrees.
> With the radials at 60ft, the low angle gain is -0.52dB at 13 degrees.
> At 60 ft, the maximum gain is 1.83 at 47 degrees. The low angle radiation
> with the radials at 1/2WL is 0.65dB less than with the radials at 1/6WL.
> That's why I chose 20ft for the height of my radials.

This part about this that is kind of strange is experimenting with 10m
verticals. I've tried many heights on these, and I've never noticed
the drastic change in pattern that you see when modeling these
antennas. OK, #1, the person/persons I used to test to were mostly
local stations that were quite a ways away. Like 20-30 miles to the
north. Now, would you agree that a local signal to a station using
ground wave would be a very low angle. Correct?
I would think so. Probably less then 10 degrees. Now, if you look at
the patterns of the average verticals, you will notice a pretty clean
pattern at low heights, but not so at 1/2 wave and up past 1 wave a
bit.
I just now ran a 28 mhz ground plane though eznec. I tried 8 ft, 16
ft, 24 ft, 32 ft, and 40 ft high. I measured the gain at 10 degrees on
each one to get an idea of the gain in DBI at that low angle. The
version at only 8 ft had .48 DBI gain at 10 degrees. 16 ft- .37 dbi.
24 ft- -0.72 dbi. 32 ft- -0.33 dbi. 40 ft- .53 dbi. Now looking at
these models you would think that the antenna at 8 ft would be the 2nd
strongest, and the one at 40 ft to be the strongest, but by an
unnoticable amount. The ones at 16,24,32 ft up you would think would
be horrible according to modeling. But in the real world, I say it
ain't so!!!
I would almost bet to my receiving station each step up in antenna
height would give an increase in signal. And by all the tests I've
done on 10m verticals I've always noticed this to be true. I have
NEVER tried to improve my signal by lowering my antenna to have a
better "takeoff angle". In all case so far, if I wanted to improve my

signal, I would either raise the antenna higher, or use an antenna with more gain. These pattern changes on verticals that I notice when modeling don't seem near as drastic in the real world. And in all my local ground wave tests, I've NEVER seen an antenna improve by being lower. Not once. I'm not saying it couldn't happen, or doesn't , I'm just saying I don't seem to notice that. I've never seen a GP at 8 ft beat one at 32 ft to far off ground wave. Not once, despite what modeling says about the TOA. So I'm kind of leary about these supposed radical pattern changes. I still think it's more important in your case to lower ground losses. IE: more radials, or more height.
I don't think the changes in pattern are quite as radical in the real world. BTW, I used fairly good grd cdx in those models that about matches this area, so the results are better than with "avg" ground .

5240. Iocm AH-4 and Manual Interface...

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-17 17:06:50 UTC
From: ATD <capt-tripps@comcast.net>
Message-ID: <3C94CC7F.F34E7019@comcast.net>
Source record: 146528
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.equipment

I've found 2 manual interfaces circulating on the web that can be used to manually control the AH-4 auto tuner. There is a simple version that is nothing more than a switch, LED, and resistor, and another that is more elaborate using a micorprocessor controller.

The designer of the micro controlled unit criticizes the other manual interface saying the 'relays may switch under load and you can not tell if the tuner has tuned'.

I'd go with the micro controller tuner in a hearbeat but have yet been able to get the details of the circuit, specifically the micro code, from the designer.

Has anyone used the simple manual interface and if so have you encountered any 'glitches'?

TIA

Andy N3LCW

Hi all,

HF, VHF, Antennas, Transmitters, Receivers, Wireless microphones, VHF FM Broadcasting. SSB, RTTY, CW, Kits, Synthesisers, EPROMS (in both digital and anali�gue circuits). Is there anything there that interests you?

Come to http://pmp3.net/harry for a lot of homebrew radio/electronics fun (if you want to be 100% serious or be miserable then perhaps it may not be the right place for you).

There are not very many links, though. Sorry! Just a few component suppliers and the odd "usefull" page.

Did you replace it with a NON-POLARIZED motor run capacitor?
That is an AC cap, and 5-mfd will not make a difference. Lot at the
tolerance ratings.

Pete

Yep, but EZNEC doesn't display the ground wave. Does that mean
the ground wave peters out and doesn't reach the ionosphere?

> These pattern changes on verticals that I notice when
> modeling don't seem near as drastic in the real world. And in all my

> just saying I don't seem to notice that.

Of course, the 1 dB difference would not be noticeable. What is
extremely noticeable for me is the average 4 S-unit advantage
that my dipole has over my vertical in (S+N)/N ratio. The noise
level is 2 S-units lower on the dipole and the average signal
strength is 2 S-units higher on the dipole.

I use the 40m vertical as the support for one end of my dipole
with the end of the dipole about ten feet from the vertical.
I'm wondering if the vertical acts as a reflector for the
dipole during off-the-end vertically polarized radiation from
the dipole. Guess I need to model both antennas together.

Believe you have it's call Lighting and jump very large area to ground or
other objects.

I've seen this on almost clear days with T- Storms off on the horizon many
miles away.. and have also seen in in wind driven snow storms as static
builds up on the antenna the longer the wire the great the discharge usually
is.. We used to use air gap static discharge to ground on some installations
while I was in the military for this very reason.

From: "Terrence R. Redding" <terry@oltraining.com>
Message-ID: <B8BA760E.164D%terry@oltraining.com>
Source record: 146540

Does this antenna look right to those on this list? I thought there was a discussion here a few years ago that dismissed the idea of a single mast diamond loop fed at the top of the mast by 50 ohms coax.

Now I see an article in QST that says the antenna works - and works on 20, 15, and 10.

Does this fall in the same category as radiating with a light bulb? Yes, you can use it as an antenna - but whether it appears to work or not, it isn't truly a good design.

Terry - W6LMJ

Hi Mark,

Has time erase old wounds? Consult:
http://www.qsl.net/kb7qhc/antenna/fractal/n1ir/k2/index.htm
and recall, if you care, a time when fractals and the k2 ruled the world and this famous ground warmer exhibited an optimized low angle radiation through what I consider the employment of earth ground as a passive, reflecting element.

This invention, of course, was discovered through itinerant model mining (unabashedly described as science), redefined with artificial constraints and posed as the poor man's solution to DX - such hubris....

Hi Bob,

Well, the marine bands (not be confused with Sousa) are used on land
and at sea. In one of our shipyards here in the snowy northwest I
find a horizontal rotatable HF dipole barely above their offices on
Lake Union.

The best shape is a circle for a loop antenna from what I understand.
You can also use it in a square configuration (Quad antenna
style)feeding it from the middle of one side with minor increases to
the total length of wire used to construct the loop. As for feeding it
from the top..... I think the diamond shaped Quad is fed from the bottom
using coax. The over all length would be about 17' diagonally.

Hi Jason,

First the concept of the bridge. It exhibits a null to the detector when all four arms are balanced with respect to each other. There are many respects and many topologies to observe these relationships; however, when you boil down the designs, they are all closely related if not identical - hence my suggestion for you to reduce those circuits as an exercise. You will find much enlightenment in such an exercise still, even after my lucid explanation. :-)

Being able to "see" an opportunity for a bridge solution for a measurement problem is ALWAYS preferable. A balanced bridge presents absolutely no load to the item being measured and by this becomes invisible to the process. Bridges bring isolation, sensitivity, resolution and accuracy. To illustrate, you may not be able to afford a DC or low AF (audio) AC meter with 4 place accuracy (not to be confused with 4 digit display); but you may, with work, build an inexpensive bridge accurate at AF to 6 places and very respectable in HF. Note, as you depart from low frequencies, instrumentation accuracy plummets, and bridge techniques become even more necessary.

Second, the balance of the bridge. This may obtained by holding the "unknown" constant while you derive its value by the inference of control settings (what you have in mind in some sense, and perfectly justified). OR, the balance may be obtained against a constant reference by adjusting the "unknown."

This second method is cheaper to manufacture, calibrate, and simple to use. The first requires cumbersome shaft coupling for critical, large component placement; and (for precision) special shielding to balance

stray coupling.

Third, the source of white noise. By strict definition, white noise is constant in amplitude at every frequency. This again is a commercial consideration in that the designer need not build an extra stable source capable of wide frequency span. This last requirement of stability, as you may now guess, is strictly required if you are to seek and hold a sharp, deep null (it is an absolute pain to chase a drifting source).

Fourth, the operation of a noise bridge. As I said, R1-C1 are the reference and you should note that the ARRL design (and perhaps the MFJ) adds a 100 Ohm resistor to the "unknown" port. This means that without ANY other connection made, the bridge is already in balance. If you observe otherwise, it means that C1 is not adjusted correctly. This presents a simple, one-time solution for that problem by simply tweaking C1. Now, once observing this verity (the already mentioned null) and adding your reactive load to the 100 Ohm resistor at the "unknown" port, you run the risk of unbalancing the bridge if that reactance upsets the effective 100 Ohm requirement. You then rebalance the bridge in one of two ways. You shift your receiver's frequency until the noise abates, or you shift the component that presents the reactance until the noise abates at the original frequency. The first method determines the resonate frequency of the "unknown." The second method forces the "unknown" to resonate at the original frequency. This, of course, presumes a parallel resonance that presents infinite impedance whereupon the 100 Ohm resistor seems to be the only component residing at the "unknown" port (and balance is assured).

Note the emphasis on parallel resonance (it simplifies this instruction). This works with traps, but is not indicative of antennas (except for halfwave). This may sound like a paradox for the intended application, so there are other considerations to be observed in either the application of the bridge, or in its design. The observance and cogitation of those differences are left as an exercise.

The upshot of this all, is that you need to think abstractly in terms of the bridge topology, its design requirements, its actual design, and its application. Reduce all design issues to the bare minimum and replace the "unknown" with a simple L-C-R configuration to determine just how well the bridge may perform. Playing with a SPICE emulator like Electronic Workbench would do wonders to illustrate these concepts.

A splitter isn't the best choice. Better would be a diplexer. This has filtering
which will keep the antennas from interacting in ways that would modify their
patterns.

5265. FA: McKay Dymek AM7 TUNER - AM / Long Wave Tuner

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-18 01:39:20 UTC
From: Daniel Simpson <dzan@qwest.net>
Message-ID: <170320021939203730%dzan@qwest.net>
Source record: 146553

FA: McKay Dymek AM7 TUNER - AM / Long Wave Tuner.

A AM7 tuner is basically a AM5 with the addition of the Long Wave Band. Used in Europe. That you can receive along the east and west coast of the US. (See Information Below)

Long Wave Information:
"155 to 281 kHz: This is another AM broadcasting band in Europe and parts of Asia. In Europe, there are numerous high powered (1,000,000 watts or more) stations here. These stations are capable of covering an entire European nation like France or Germany with reliable signals around the clock. Although ionospheric propagation is not good at these frequencies, the high powers used means that many of these broadcasters can be heard along the Atlantic seaboard during the fall and winter. Best reception is usually from local sunset to about 0600 UTC. A few long Wave stations in Asiatic Russia can be heard on the Pacific Coast beginning an hour or so before local sunrise."

A Detroit Michigan user said:
"I have an AM-7 and a DA-7. They make a nice pair together. Unfortunately, there's not too much long Wave possible except on a few winter nights when I can pick up some of the powerhouses from Europe on the AM-7. I have heard Morocco, France, and BBC on longwave here in Detroit. In fact, this winter, I got them pretty regularly"

SPECIFICATIONS:
* Two Band High Fidelity Solid State Tuner
* Frequency Range: 540-1605 kHz. Standard AM broadcast band,150-300 kHz Long Wave
* Sensitivity: 6.0 ,uV for 10 dB signal to noise ratio on Long Wave Band. 3.0 uV for 10 dB signal to noise ratio on Standard AM broadcast band.
* AGC Characteristic: Less than 6 dB output variation for an input level change of 10,uV to 10 mV.
* Bandwidth: -3 dB RF Narrow - 6 kHz; Wide - 15 kHz
* I.F. Rejection: 45 dB
* Audio Frequency Response: -3 dB @ 15 Hz, 7500 Hz
* Audio Whistle Filter: 9 kHz
* Distortion: 1 kHz @ 30% modulation: 0.5% 1 kHz @ 50% modulation - 1.0%, 1 kHz @ 80% modulation - 1.5% (1 mv @ 1 MHz input, wide & distant mode).
* Audio Output: Standard: 1V RMS- 5K output.
* Shipping weight: 12 lbs. (5.5 Kg.)
* Dimensions: 17-1/2" x 10" x 3-1/2" (43cm x 25cm x 9cm)

Features

The McKay Dymek AM 7 TUNER is an all solid state high fidelity AM/Long Wave tuner combining extremely low distortion with excellent sensitivity, selectivity, and a wide audio range. The AM 7 is compatible with professional studio equipment as well as high fidelity "home" sound systems. The low profile black and teak cabinetry makes the AM 7 an attractive addition to any system or decor.

Broadcasters all over the country report excellent results using Dymek Equipment as low cost monitors. As one station executive wrote, after using the Dymek as the standard, "our signal was as close to 'FM on the AM band' as we could get".

reception from local or distant stations is assured by a choice of narrow or wide bandwidth selections at the front panel. To prevent an overload of the "frontend" that may be caused by strong local stations, an attenuator in the antenna circuit has been included. An illuminated, easy-to-read tuning meter aids in ease of tuning and is standard equipment on all Dymek tuners.

Remarkable selectivity is achieved with two eleven element ceramic filters. A whistle filter eliminates most bothersome noise common to AM listening. Distortion is low and sensitivity helps pull in those distant stations; lets you take advantage of AM's natural long range capabilities - hear stations which were previously unlistenable. Wide and narrow bandwidth selectors assure optimum local and distant reception. Illuminated tuning meter.

The Dymek outreach for perfection in AM reception has produced the Am 7. Unlike conventional AM tuners, the AM 7 allows full and accurate reproduction of transmitted program material. For the first time, AM reception is not limited by the receiving equipment The complete transmitted fidelity may now be fully enjoyed and appreciated.

McKay Dymek is the leading producer of AM high fidelity receiving equipment. Authoritative hi fi magazines agree that the quality of AM reception provided by Dymek equipment is truly excellent. This fact is further established by the acceptance of our products by scores of AM broadcasting stations throughout the United States. Many stations use more than one Dymek tuner to monitor and insure their transmitted quality.

For many years very high quality AM transmitters have been operating, but due to the mediocre performance of available AM receiving equipment, most high fidelity experts believed AM reception to be of inherently poor quality.

It is truly a difficult challenge to design and manufacture a tuner capable of high quality AM reception. McKay Dymek engineers accepted this challenge and, after expending great effort, have succeeded in the design of the AM 7.

The McKay Dymek AM 7 tuner is a precision, solid state AM instrument of the highest quality.

Innovations have been engineered to provide:

Very low distortion even at high modulation levels using a unique hot carrier biased diode detector.

Extremely wide frequency response through the use of expensive ceramic filters.

High sensitivity for reception of weak, distant stations.

Once you have listened to AM radio on the AM 7, surely you will agree with our many satisfied customers: the AM 7 is a truly superior addition to any high fidelity system.

RIF SECTION Dual antenna connectors are provided on the rear panel. An RCA type connector is provided for coaxial cable antenna systems. There is also a set of terminals for direct connection to a longwire antenna and external grounding.

A Dymek AM 7 tuner represents the very best in AM/Long Wave listening. Try it!

Note:This unit needs an external antenna to work I used a terk AM antenna with this unit and it worked well. I am also putting this antenna up for sale. Check for it on ebay. and will need a Long Wave Antenna to receive Long Wave. Like a Mckay Dymek DA7 Antenna or a QUANTUM QX PRO LOOP.

This unit has some minor scratches on the top also a scratch on dial under czech USSR (could be fixed with black paint or marker from the inside) and missing ground plug (see pictures). Otherwise it is in Great Shape!

I accept Paypal, Billpoint & Money Orders. $12.00 for shipping-Continental US only. Insurance optional at buyers expense. Winner to pay within 7 Days of auction close. Email me with questions.

Thank You and Good Luck!!

5266. FA: Terk Advantage AM Antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-18 02:01:52 UTC
From: Daniel Simpson <dzan@qwest.net>
Message-ID: <1703200220015264 51%dzan@qwest.net>
Source record: 146555
Cross-posted to: rec.radio.amateur.antenna,rec.radio.amateur.boatanchors,rec.radio.amateur.digital.misc,rec.radio.amateur.dx,rec.radio.amateur.equipment

FA: Terk Advantage AM Antenna

Finally an AM antenna that is truly beautiful!

When appearance is an issue you finally have a great choice! It has most of the power of a Select-A-Tenna plus it is a handsome addition to any decor. It comes with wires like the Select-A-Tenna Hardwire model for direct connection to your stereo or can be used like the regular model Select-A-Tenna. It certainly blows away any of the smaller antennas supplied with a stereo. Size: 9.5ï¿½ high.

The Terk AM Advantage AM antenna dramatically improves the AM reception from any receiver, tuner or portable radio. Its unique passive wireless technology eliminates the need for connectors, batteries and power cords ï¿½ simply place the AM Advantage near the receiver or radio.

The AM Advantage combines wireless convenience with advanced tuning technologies such as Terk's exclusive Pin-Dot Pre-Tuningï¿½ that zeroes in on even hard-to-get stations by tuning the antenna to the station's frequency.

Features:

* Pin-Dot Pre-Tuning dial adjusts antenna to a specific frequency for best reception of individual stations
* Compact design allows easy placement
* Non-skid base keeps antenna in place during adjustment
* Reception pattern: Omindirectional
* Dimensions: 9.5"H x 9.5" W x 2.5"D
* Wire For Direct connection

AM Advantage Q&A
Does this antenna need power for it to work? Also, how can I connect it to my radio?
The AM Advantage is designed for "wireless operation"--that is, it does not need AC or battery power and will actually provide signal to your radio or receiver without having to be connected with wires. However, if your radio or receiver has connections for an external AM antenna, we supply a wire with the AM Advantage to connect the antenna to the input, should you choose to do so. The solid black wire connects to the terminal on the radio or receiver labled "AM in," while the wire with the white stripe on it connects to the terminal labeled "ground."

Can I extend the wire on my AM Advantage to place it on a windowsill or somewhere away from my receiver?

You can extend the wire with by splicing it with insulated doorbell wire, which is available at any do-it-yourself electronics or hardware store. However, we do not suggest doing this, because the length of the wire is calibrated to correspond with the tuning dial on the AM Advantage. When you extend the wire on the AM Advantage, you also change the resistance of the antenna, which will cause the station indications on the dial to be inorrect.

Why does my antenna work better when I touch it?
When you touch the antenna with your feet on the ground, your body is actually acting as a giant antenna and affecting your AM Advantage's reception. You have to let go of the antenna and move away from it to determine its reception performance.

Can I make the wires on my antenna longer?
No. When you make an AM antenna lead longer, you make it more susceptible to interference. The longer the lead, the more interference you are likely to hear. Also, lengthening the cable will change the impedance of the antenna and degrade reception performance.

Why does the antenna work better when my radio and antenna are next to a window?
Many building materials can affect AM and FM signal reception. Metal, brick and stone between the radio station and the antenna will decrease the strength of the signal. to the antenna. However, glass does not block radio signals, and locating your antenna next to a window allows the antenna to receive a cleaner, stronger signal.

This unit is in good to great shape. It shows some scuffs in the rubber base. and that is all.

I accept Paypal, Billpoint & Money Orders. $9.00 for shipping-Continental US only. Insurance optional at buyers expense. Winner to pay within 7 Days of auctions close. Email me with questions.

Thank You and Good Luck!!

However, glass does not block radio signals, and locating your antenna next to a window allows the antenna to receive a cleaner, stronger signal.

This unit is in good to great shape. It shows some scuffs in the rubber base. and that is all.

I accept Paypal, Billpoint & Money Orders. $9.00 for shipping-Continental US only. Insurance optional at buyers expense. Winner to pay within 7 Days of auctions close. Email me with questions.

Thank You and Good Luck!!

You need to look at the Radio Shack home page and search on that part number.

i.e.:

http://www.radioshack.com/ProdSupport/DocumentDetail/DocumentDetailIndex.asp?URL=http://support.radioshack.com/support_electronics/38410.htm

BTX-124 VHF FM Business Band Transceiver
(190-1205) Features Faxback Doc. # 38411

Your RadioShack BTX-124 VHF FM Business Band Transceiver with CTCSS is a
portable, two-way business radio service transceiver that you can carry
almost anywhere. The transceiver is compact and light, making it an
ideal choice for your business needs.

Your transceiver has the following features:

Programmable Channels A and B - let you operate the transceiver on two
different frequencies.

Preset Frequencies - let you quickly begin operation on either
154.600 MHz (Channel A, green dot) or
154.570 MHz (Channel B, blue dot).

PLL-Controlled Circuitry - provides accurate and stable channel
selection.

Adjustable Squelch - helps eliminate noise between
transmissions.

CTCSS (Continuous Tone - helps reduce interference from other
Control Squelch System) systems in the area operating on the
same frequency.

Built-In Modulation Limiter - automatically adjusts for a wide variety
of
Circuit voice levels to ensure an understandable
transmission.

High/Low Power - lets you save power by selecting a
suitable
transmitting power for long or short
distances.

Battery Low and Transmit - shows the battery pack's condition and
Indicator lights when you transmit or receive.

Removable and Rechargeable - lets you use one battery pack while you
Battery Pack charge another (additional packs
available).

Supplied Battery Charger - conveniently recharges your transceiver's
battery pack.

Earphone Jack and External - let you use an earphone or external
Microphone Jack microphone to help ensure understandable
communications in noisy areas.

Belt Pouch - protects your transceiver and lets you
easily carry it on your belt.

We recommend you record your transceiver's serial number. The number is
on
the back of the transceiver.

Try searching on the model number at radioshack.com under advanced search.
There is much more info there also.

jester
i dont know why know one you asked knows about that radio its on radio shacks website i took this number 19-1205 that you posted and did a search and it came back with all sorts of info on it what you have is a VHF business band radio i am sure if you look around there you could find the manual you could download but dont be surprised if you cant modify it radio shack doesnt buy radios from any company that can be modified to work outside the band they are set to
good luck
oh there website is
http://www.radioshack.com
then in the search window type in that number then click the HERE link and off you go

This assumes that the test prototypes are actually constructed correctly.
There is no guarantee that this is true.

> The point here is that there is really nothing [new] to the EH antenna. The
> tests do not validate the claims of the EH "inventor" because the claims are

I don't think there is anything new about the EH antenna either. But
the only way to tell for sure is by testing a sample provided by the
inventor. Testing antennas built by others proves nothing except that
those antennas did not perform well.

I wish that could be done, so the EH can be relegated to the "mythical
antenna performance" category to which I believe it belongs.

I am about 45 feet up and 15 feet above a tin roof. Front to back is not great, especially on 20, but there is plenty of front to side. It is hard to hear a change of one or two S units as QSB can be 20 db. Watch the meter carefully. Try listening some more and make a few more comparisons. I think you will find the antenna is performing better than you are giving it credit.

You might want to modify the fraudulent description of the frequency range you have given it. My Celwave (and Tessco and Hutton) catalog says it is 18 MHz wide, manufactured somewhere between 118 and 174 MHz, like either of the standard models, 146-164 or 154-174 MHz. Where on earth did you get the idea it would work from 25 to 299.9? From the catalog index? Sorry, it doesn't work that way.

Doesn't matter. All I'm showing is that the very low angle radiation doesn't seem to just fizzle out as you would expect if you went by modeling alone. I would think most ground wave type stuff on 10m is below 10 degrees or so. If the antennas at 1/2-3/4-1.0 ,etc wave up were as bad as the modeling seems to show, then they should be fairly lame to low angle ground wave stuff. That doesn't seem to be the case in the real world.

My noise was a bit higher on the vertical, but not too much. It didn't matter as the stronger signals overrode the extra noise. The s/n ratio to dx was much better on the vertical here. If the noise is 2 s units higher and the signals are 3-4 s units higher...That was the case for me except I don't think the noise was even 2 s units higher in my case. Maybe 1. Sometimes they were about the same if it was real quiet.

I doubt it really being they are at right angles. There may be some interaction, but not enough to matter I bet. MK

I was referring mainly to elevated verticals. But I don't doubt you
can use the earth as a reflector, but I bet there is loss involved.
It's not a route I would want to take. MK

I take the opposite point of view. The EH antenna makes claims that contradict known antenna theory. Therefore, it belongs in the "mythical antenna performance category" at the very outset, and remains there until good data can be provided that justifies its being removed from that category. To permit the opposite is like saying that we should believe Lepreuchans or perpetual motion machines exist until proof is provided that they don't.

Roy Lewallen, W7EL

>
> Preset Frequencies - let you quickly begin operation on either
> 154.600 MHz (Channel A, green dot) or
> 154.570 MHz (Channel B, blue dot).

And Radio Shack can reprogram it for any other two business frequencies within its reach. If I recall correctly, they don't believe it reaches the 2m ham band. Whether it really could reach the 2m ham band isn't important unless you can find someone to reprogram it to a ham frequency.

The two frequencies that originally come programmed in this model radio are FORMER itinerant business band frequencies that used to be licensed under Part 90 of the FCC Regulations. Those two frequencies were withdrawn from Part 90 in November 2000 and are now allocated to the Multi-Use Radio Service (MURS) which is a licensed-by-rule service under Part 95 with strict limits on ERP and bandwidth.

Why does it matter where a one wavelength loop is fed (other than for
selecting polarization)?

On a one wavelength loop, in free space, any point would be as good as
any other. If it is close to ground, then different feed point would
have slightly different impedances. The shape of the loop may have a
smaller effect. Otherwise I don't see why it would matter much.

Hi Bill:

I must agree with Roy.

The issue is not for others to prove that the EH antenna does not work as claimed. This is an exercise in which the "inventors" can always claim that the antenna was not constructed properly. (I place "inventors" in quotes because the antenna is a simple small conical monopole antenna over a small ground plane. Its performance characteristics have been well known for many years.)

Given that the "inventors" claims defy widely accepted and proven antenna theory (and in most their claims defy simple logic), the "inventors" must prove their claims. The burden of proof rests on their shoulders.

Source record: 146481

What I look for in a program which generates radiation patterns are those patterns proper to the antenna itself and its immediate environment. i.e., before propagation loss in its many directions and elevations sets in.

I would prefer to make my own predictions of what happens to the somewhat more distant radiated fields by taking into account propagation loss along the ground and through the ionosphere.

The two aspects are independent. They are as different as the generator is from the transmission line. There's no need to confuse them. Now folks, KISS and make up !

I'd agree, except the Butternut is (supposed to be?) DC grounded; ie, mine has a coil between the base of the antenna itself and ground that 'theoretically' bleeds off the static charge. Did the coil go away with the new radial system?

I do not know how the size of the 450 compares to the 800sdx. But ...

I had to remove one diagonal to get a Yaesu 450 in to my Rohn 25. I had to redrill the plate to make it match. In fariness, this was a very old plate and might have had some non standard spacing. ALSO the bolts that came with the rotator were TOO SHORT. They warn you against bolts that are too long damaging the rotator, but then shipped bolts with it that engaged only 2 turns when put through the plate. I went to the hardware store and found a combination of standard bolt length and washers that gave me a good engagement of the threads with out bottoming out.

The Alinco EDX-2 is an automatic end-fed-wire tuner that integrates with a couple of Alinco HF radios, including the DX70-TH.

I am aware that some folk have used this tuner independently of the Alinco transceivers.

Has anyone information on the protocol for controlling this antenna tuner so that I can make a controller that will allow it to be used safely and reliably with other radios?

Thanks... Owen

I installed a similar antenna for a neigbor who is also a ham. The best test we could find was between our two stations seperated by about 300 yards. I made measurements using my s-meter and a calibrated attenuator. We found the antenna met specs or greater when at a height of 20 fett above his roof of 20 feet so 40 feet total. The qsb on 20 15 and 10 is usually too great to permit an accurate measurement and s-meters are notorious for their inaccuracy so hence the attenuator.

Vito,
In the order of 'likelyhood;

1. a. Radio and tuner connected incorrectly.
b. Tuner, antenna, and ground connected incorrectly.

2. The 'random wire' was too random, tuner was unable to
find an acceptible match.

3. Something wrong with the radio.

4. Something wrong with both tuners.

Got to be one of those, or a combination of them. The
only other possibility is 'operator error'.
Hope you get it worked out...
'Doc

Which is why I stated - "testing a sample provided by the inventor". That
way, the person has no way of weaseling out when the test fails, due to
claims of "improper construction".

From: VA3ATD <a.duffy@sympatico.ca>
Message-ID: <3C967760.80406@sympatico.ca>
Source record: 146494

I never said it mattered. I was merely pointing out that the driven elements of a quad style antenna and a diamond configuration quad antenna had the feed points at the bottom. Why have the extra coax? Matching purposes?

Terry seemed to be questioning the validity of feeding it from the top. ("Does this antenna look right to those on this list? I thought there was a discussion here a few years ago that dismissed the idea of a single mast diamond loop fed at the top of the mast by 50 ohms coax.")

But if it were a 1/2 wave loop, isn't the maximum field strength opposite the feed point (unless the opposite corner is open at which time the reverse is true)? If this is the case, then feeding from the top might not be such a good idea. But also on 10m the loop would become a full wave antenna at which time the feed point wouldn't matter. I've never heard of a 2 wave length loop (does one exist and what would be the effect on the pattern and impedance).

All this in mind, I would have to say that if it's a half wave at 20m then it might be best to feed it from the bottom and on 10m it wouldn't matter.

5312. Re: April 2002 QST - 40 meter loop

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-19 01:45:17 UTC
From: richardharrison@webtv.net
Message-ID: <16227-3C96982D-77@storefull-2395.public.lawson.webtv.net>
Source record: 146498

Tony, VA3ATD wrote:
"Terry seemed to be questioning the validity of feeding it from the top."

The first figure, 10-1(A) in the large loop chapter in ON4UN`s book may show why the QST loop is fed at the top, and not the bottom.
Current is stronger adjacent to the feedpoint than it is on the far side of the loop. Significant energy is radiated on its way to the far side.

The closer an energized wire comes to the earth, and the stronger the excitation of the wire, the more the earth`s energy toll. The loss in extra feedline to reach the top probably is less than the extra energy loss in the more powerfully excited antenna elements near the earth, were the antenna bottom-fed. A taller support pole might change this trade-off.

ON4UN says:
"The radiation resistance of an equilateral quad loop in free space is approximately 120 ohms."
Impedance is affected by proximity and quality of earth near the loop.
ON4UN has charts in "Low-Band DXing".

Best regards, Richard Harrison, KB5WZI

> Even with this minor problem the antenna is still great.

Ron,

I agree with Craig. I love the antenna. The F/B is not great,
as you noted, but F/S is. I get about 1 S unit difference F/B,
and about 3 S units difference F/S. If you believe my S meter
is calibrated, linear and accurate, maybe that means about 18
db F/S and about 6 db F/B. I have no clue - but I do know
it makes a difference. Mine is mounted only about 5' above
the peak of my roof - the peak is 23' above ground.

We've looked over the site, but they don't tell us anything about what we really want to know.
inside the radio, there are 10 DIP switches and what appears to be a reset button of some sort.
The service techs over here don't have a clue and aren't about to touch it.
The paper manual,
the PDF files, and tons of sites, so far, have not offered any explanation of these pins or
how to set them. All I really know about them is that they where all set to off and depending
on how you set them and work them, if you press the reset button, you get a different
series of beeps. What we really wanted was to see what the pin sets were for and if
the radio can be reset to a different freq with them, preferably to something we're licienced
for... <GRIN>, or are these just some pricy paperweights...

Thanks for all the input... sluggo286@yahoo.com

Source record: 146501

"Works like it should" is a HIGHLY relative term - and if YOU are suggesting that a ball mount
somewhere at mid-point on the SIDE of your van will deliver performance AS GOOD AS if the antenna
was mounted in the center of the ROOF - well, yer simply kidding yourself! SURE, you MAY make
contacts and receive signal reports that satisfy you - but UNLESS you have actually run tests with
that SAME antenna mounted on the top of your van, out high and in the clear, you have NO CLUE as
"how it SHOULD" - or COULD - function on that same vehicle!

And concerning statements as to "waste of time and energy" - to SOME of us, obtaining an additional
S unit from our antenna because WE have done actual tests and research as to the BEST placement for
our antennas is HARDLY a "waste of time and energy"!

What YOU are happy and satisfied with in a mobile installation and on-the-air reports probably
differs SIGNIFICANTLY from what some of the REST of us will "settle" for!

This seems fairly straight forward. According to my Radio Shack catalog their business band radios "can be set by a RadioShack Service Center to nearly any VHF business frequency from 150.775 to 157.740 Mhz." The catalog also says "FCC license required." No testing is needed for the license, so you're not allowed to service the radios.

In other words, it is illegal for you to reset these radios, yourself, but if you get a business radio license and have a RadioShack Service Center set the radios for you, you'll have working radios.

To apply for your business radio license, go to the www.fcc.gov site, click on "Forms" and then click on "600" and "Download Instructions."

Cheers

Bob

Good day,

Doing a google search
http://www.google.com/search?hl=en&ie=ISO-8859-1&oe=ISO-8859-1&q=homebrew+cellul
ar+yagi yielded very few "valid" links, but the top one may be something to look
at. A little OT but I did buy a great one for less than $100.00 and boy did it
work great on my old Motorola Bagphone!

You can always try a Hustler short mast with 17M resonator mounted in
the center of your van. When I had a minivan I used this combination
with resonators for 10-40M with very good results.

Be sure to use a spring at the base.

Source record: 146510

Hi everybody,

what a pity ! I was surfing the EH antenna official web site today, and I noticed that the site had been updated on March 18th. I said to myself "wow!, maybe we can eventually find the results of the AM tests..". Guess what... NOTHING at all.
Just another updated release of the "theory" behind the antenna, with the same hilarious approach to electromagnetic fileds.. today's best is the sentence: "If the phase is corrected, the "capacitor" becomes a leaky capacitor". Guys, that's really GREAT !
When will they understand that they CANNOT change the physical properties of an antenna by changing the circuit to which it is connected ?? You wonder which kind of engineer Ted is ....
Best 73,

Michele IZ2EAS

Those switches may be for the CTCSS tones.
Usually a binary coding as far as the switches go.
Most VHF High band units like that are on what was referred to as the high split, and are nearly impossible to convert to the 2 meter ham band, at least AFAIK.
But it's been years since I worked on commercial stuff...

Follow up to my last reply:
Found switch in parts as follows...
S201 11878030 SWITCH,ENCODING DIP D10GE S90067
Would look to me that this is the CTCSS encoding switch, but I do not know
exactly how to program your unit(s).
A service manual would tell, I assume, but getting one looks like it might
be a hassle.

> Did the coil go away with the new radial system?
>
I think the problem is caused by a missing DC ground of the antenna. Of
cause the 80m coil will DC ground the antenna if it is present.

According to the instruction masts and supporting parts must be grounded.
The base of the HF6 must therefore have DC connection to ground.

For printing out all those sample antenna radiation plots :-)
CL, just go to ebay and search 'epson cartridges' or whatever. There
are more discount cartridge sellers than there are lawyers. If you
don't like buying via ebay, most of them will have a link to deal
direct.

>

I'm not sure how a 1/2 wave loop would work. I think it might have a very high impedance and be hard to feed. Some one who is more knowledgeable than I will have to answer that one.

I have heard of a 2 wavelength loop. I think Kraus mentions it in Antennas. I don't have my copy here at work so I can't look it up, but as I recall it has quite a few lobes in the pattern. It is not as good for a directional antenna as a full wave loop and would probably be best placed in a horizontal plane

In general for a loop antenna, I think you would want to stay away from odd multiples of a half wave. For a dipole you want to use the odd multiples.

A full wavelength loop, regardless of the length, can be fed anywhere depending on the polarization you want. At the bottom will give horizontal and on the side will give vertical. Certain shapes, however, may have slightly different characteristics. My dad had a 40 meter delta loop (pointy at top) that he fed a few feet up from the bottom on one side. As I recall the horizontal bottom wire was only about 8 ft off the ground, and this was supposed to do something good. I don't recall the details, but this was a real performer! Perhaps someone else will. The design was in Ham Radio or QST back in the late 70s, I think.

Usually they use log periodic Yagis for this, because of the bandwidth involved.

And don't forget to make it vertically polarized,or you will loose 30 to 40 dB before you even get started!

You could also consider a parabolic reflector, or possibly even a simple corner reflector, with a single dipole as the feed antenna.

What band? 800 MHz or 1.8 GHz?

Hi:
If they were the built in kind of tuners, they are meant to tune over a 3 to
! SWR range. It would be a wild bit of luck to have a random wire fall with
in that range. Other wise if it's a external tuner, it still needs a ground
to work with. It could be a car body or a wire laying on the ground. But
with a radio sitting on a bench it would again be just good luck if it
worked. Any way the to handle this is to make the "random" wire a bit longer
(best) or shorter until it works. Never make the "random" length close to a
half wave as the Z at the end of that almost any tuner will have trouble
with.

Imagine a system floating in free space. For simplicity, we use a folded
dipole or a dipole with a delta match. You know, the kind of antenna
where
You do not need an insulator to attach the antenna to the boom or Your
mast- it's simply to bolt the middle of the radiating element directly
to
the mast. But, in free space You of course do not use any mast, just
the radiating element. The antenna is conneced with a random feeder to
a transmitter, which is on.Please, will you tell me how to figure out
what
is the antenna and what is the feedline/rig/power supply. As I am an
alien from outer space, I am not able to see the physical shape (or feel
it), but to my help I have the possiblity to detect field-strength
with my senses.

Hey since I am new to this newsgroup I dont know if this antenna has been talked about much but does it work?
http://www.g3tpw.ukgateway.net/
I hope so.
Has anybody put this desigh into one of the antenna programs to 'see' how well it works?
But most important has anyone ever used this antenna?
Please respond if so!
Also on the website the creator said it has been reviewed in several magazines.
They state that they used to advertise up until 1993 and the last magasine to review the antenna was in 1996.
Does anyone have these reviews?

From: rafael <rafahol@hotmail.com>
Message-ID: <a77mg2$5ut$1@news.tudelft.nl>
Source record: 146373

Hello People,

Does anyone know how to match a triangular patch antenna using the microstrip feeding method (because of the fact it has to be used for mobile phones, therefore the feeding network has to be planar)?
For my thesis I have to design a triangular patch antenna resonating at 2.14 GHz with a VSWR< 1.9 for the band
2.11-2.17 GHz. Calculating with standard formulas gives me the length of the side of the antenna but the bandwidth
is very small, usually 1%. My tutor suggested me to feed this antenna at one of the edges to obtain an improvement in bandwidth
and to use for example three sections of microstrip lines with different lengths and impedances feeding the antenna at the middle of one of the edges.
Is there a simple software package available which allows optimization of the different lengths and widths of the three section of microstrip lines?
Is there already a design available from literature for such a equilateral patch antenna??

Thanks already for answering my questions, Rafael

I have no problem thinking the Cobweb ant. will work, but I do
have a problem with 1/2 wave loops being omni-directional.
Most normally they exhibit forward gain towards the feedpoint
which takes away from the other 3 sides.

You could build up a mono-bander pretty easy with pvc
pipe and give it a try, that gives you results that beats anyone's
opinion.

Sorry Val, but maybe your question is too difficult for my simple mind... I really don't understand what it all has to do with "ground"... In fact, you don't have to distinguish between antenna/feedline/rig... you'll just have parts of your system that radiate more (the "antenna") and parts that radiate less (the feedline)... in fact, all you need to calculate the radiation is the distribution of the electrical current on your conductors. What you call an "antenna" is just something that radiates quite efficiently... again, I cannot see what "ground" has to do with that... unless we are biased by different definitions of "ground".

I would, indeed, mount it on the left side of the van and high enough to get the coil and
whip above the roof. I *think* the 17 meter hamstick would allow you to do that without
hitting *too* much stuff. I am not a fan of hamsticks, but you may get satisfactory results
if you do the above things.

>
> KA3DWW

First things first:

What type of counterpoise (ground) did you have to work the random wire against?

If you don't have a counterpoise to work against, don't expect it to tune.

I see this all the time on sail boats that do not understand anything about antennas and wonder why they can't transmit when they do not have a ground system to work against.

==========

If you do have an adequate ground...

Try tuning at low power and then change to 100 watts and see if the tuner maintains lock.

SGC sells a kit for their SG line of tuners that locks the tuner settings while the tuner lock switch is engaged so that it does not attempt to re-tune on every transmission. If your candidate tuner attempts unsuccessfully to tune up on higher power once it has correctly tuned on low power, you may need "tuner lock" capability.

A lot of automatic tuners are "automatic sort-of" or "automatic sometimes". The better your ground, the better they work!

DataProducts Corporation (_long-time_ reputable computer company) sells recycled and refilled cartridges for the more popular models of inkjet printers. In my area, they use Staples (an office supply store) as an outlet. In the case of my particular HP printer, the DP refills are about 20% cheaper than the HP new. DP represents the refilled cartridges as being equivalent to new cartridges and as being warranty-compliant. My experience so far is excellent. I don't have good enough data to prove cartridge life, but it seems to be OK.

It does not mater if the elements are inuslated from the boom or not. HOwever, the calculations will be differant if they are connected or insulated. At 30 mhz and below there is probably not much differance but at higher frequencies the boom has an effect of shorting out some of the length of the element so the elements need to be of differant lengths on insulated vers noninsulated booms. One thing is that if the elements are not insulated from the boom they need to be firmly attached. If not they can cause noise on the received signal as they flex in the wind and possiabley cause harmonics to the transmitted signal as a diode junction might occure as the elements oxide.

As far as the specs due to gain and F/B ratios I think they are pulled out of the hat for most antennas. Some are in refferance to dipoles, some to the isotropic and some are calculated counting on the aditional gain due to ground reflections. The main thing that determins the gain is the length of the boom and next is how the elements are spaced and the length of the elements. Many times the longer boom length antenna will have more actual gain than one that has a shorter boom but more elements.

Icom automatic tuners (and perhaps others) automatically turn down the transmitter power output to a few watts until the tune up process is completed. Its a safety precaution.

If the TX power for some reason cannot be reduced to a low level the tuner inhibits itself from starting. It is protecting itself.

There is a DC lead from tuner back to transmitter which takes control of the ALC.

I've got a tri-mode cell phone and bought an 800-900MHz yagi made by
Wilson Electronics (model Y8009EL). (OK!. OK! Cut the crap. I was in a
hurry for a solution.) Antenna, coax, cell phone adapter, etc. about $100
at the local ham/CB/scanner/obscene-car-audio shack. Put it in my office
(we're in a _huge_ cell phone hole here) and aimed it at a tower. Works
very well. Only complaint (not the antenna's fault) is that my cell
provider prefers 1.8GHz, so sometimes there are issues with regard to missed
voice-jail messages since the 850MHz absolutely dominates the 1.8GHz when
the antenna is connected.
Have you looked at sites such as
http://www.netscum.com/~clapp/wireless.html ? They are dealing with
wireless LANs at 2.4GHz, which isn't that different from 1.8GHz cell in
terms of size and technique. Really cheap solutions there using an "N"
connector, all-thread, washers and a Pringles can. Claiming 12+ dB plus
good noise numbers. Going to try it myself!!! Compensation for freq
shouldn't be too tough. Check a site like
http://www.kvmo.net/~aschmitz/antennas/calcantenna.html if you need help
with the calcs.

Val ha scrito:
"NO antenna can work without a ground. Period. Not even in satellites.

Val also wrote:
"---what is the antenna and what is the feedline / rig / power supply?"

An antenna must be part of a complete circuit for a radio input or output. In the case of a transmitter, energy exits one output terminal and enters the other.

In a loop antenna connected with a radio, a complete circuit is obvious.

In a dipole, you see an open-circuit because the coupling between dipole elements is not visible, but we see the effects of invisible fields. We see electrostatic fields attract small particles nearby. We see magnetic fields attract magnetic particles nearby. These fields exert unseen forces. In the dipole we have a complete r-f circuit because the antenna accepts current that we can read on an r-f ammeter. Dipoles have mutual coupling between their elements. No ground is needed for this coupling to complete a circuit. Displacement current and inductive flux link the parts of a dipole. No physical contact is needed for current between parts of a dipole for current flow. Current flows wirelessly. Some of the energy this current represents gets away as radiation.

The balanced antenna needs no ground.

The unbalanced antenna completes its radiator circuit through a "ground" which replaces 1/2 of a dipole, but functions differently from a dipole. A proper ground does not radiate because the energy flowing into it flows in diverse directions which balance to zero In their field effects.

The salient part of an unbalanced system which is supposed to radiate is the antenna.

The feedline is the energy conduit between the radio and the santenna, and this is usually not supposed to radiate.

The rig is the radio which needs the antenna, feedline, and power supply to operate properly. It is the transmitter and/or the receiver.

The power supply is a source of energy a rig can convert to r-f and other frequencies.

Best regards, Richard Harrison, KB5WZI

5346. Re: EH Antenna: any news ?

Newsgroup: rec.radio.amateur.antenna

Source record: 146383

Hi to all the Ng EH antenna readers.

I was out for a vacation...out from any antennas...hi.:-))

I was REALLY surprised to read some comments.
about the test was supposed to be held....

1) WE were ready with any EH antenna waiting for the test.
2) Francesco and the others never asked us anything about
3) They never told us anything about it
4) i think the english of Francesco is very good. I think is clear THEY have some problems NOT us. ok?
but...
5) I was surprised to read NO words on this sense from my collegues.....answering YOUR sarcastic comments.
shame on them.
many hams here are negative minded oriented....nothing can change their menthality.

Answering to Richard I am asking to many italians hams to report here their SUCCESSFULLY experiments with eh antenna.
I am still saying we have HERE a lot of top success stories.
again I am speaking of real data measurements....

since I CAN'T speak on this topic because I am the part involved, I hope you can discuss with some experts ham soon about it.

I can still repeat:
1) the eh antenna works as claimed
2) the efficiency is more than 95% respect to a dipole
3) th eh antenna is working exactely as the dipole. BUT here the E and H fields are also in time phase AT the antenna.
4) I am collecting all the success stories....I have reached number 60. Every day I am getting one more on the average.
5) for the first time in the humanity history the USA "guru" are back....because the pushing guy is a italian one. (actually is the second....the first was Marconi)

when every one of you will have a working eh antenna on his shack, probabily will start to open the eyes.

Hoping you will start to discuss with some good italian experimenters (not warming chairs only) soon, I wish you all the best.

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-19 21:22:13 UTC
From: Lou <tech@dp.net>
Message-ID: <a78c3g$l2s$1@news.dp.net>
Source record: 146387

1 - Instruction and Assembly manual for MFJ 1796 Vertical Antenna. A water mark is on the bottom, otherwise manual is in fair and readable condition. $1.25

1 - Batch of parts for MFJ 1796. Mounting brackets, some of the cable, etc. Whatever is there, all for $10.00

1 - Pair of "small" white porcelain insulators - $2.50/pair

2 - CB/10 meter verticals. NEW IN BOX, but SOLD - AS IS. They are the ones sold by R.S. Info in boxes opened of previously sold stock was that of Antron 99. $35 each

1 - MFJ 5/8 wave 2 meter "base" antenna base - for parts. $2

Much more. IF you don't need anything today, save this for another day. Things come and go here. Like a perpetual Hamfest/Fleamarket.

I wish I could have heard a strong signal on my vertical. There weren't
any that were as strong as my dipole. I sacrificed my garden for 8 buried
radials for that vertical. I just today took down the vertical and ripped
out the radials. Time for a new garden.

Has anyone mounted a large VHF/UHF (over 40 inches tall) antenna on an extended cab, K1500 Chevy Pickup? If you have, please tell me what mount you used and were there any challenges to mounting it? I'm considering a permanent mount for a large Diamond antenna I have.
Diamond wasn't any help (online or tech support).
A couple of the ham radio equipment dealers didn't recommend it (wind load on a roof mount was of concern).

Any ideas?

Thanks,
Matt, N8UVF

http://www.hamstick.com/hk.htm

Works for me for HAMStick/LakeView's 2M collinear. Of course, my pickup's
an '85, so I don't mind the hole in the roof liner for the coax...

If you don't want the hole in your roof liner (does your cab have one?),
there are other similar types out there that have the coax attached. You'll
have to remove your roof liner to install it, then replace the liner, run
the coax down an A-pillar or something, to the rig.

if you are worried about wind load i would suggest the 3 or 4 magnet mag mount
once that thing is stuck to the roof you shouldnt have much worries about it
coming off

Hi Raf,

I have seen your very same question appearing and disappearing on the www.eng-tips.com forum twice now. Each time I have responded, and the thread has then disappeared. Very very strange. IIRC, on those (temporary) threads, you had mentioned that the patch in question was a Sphincter Gasket, no that's not the right term..., a Sierpinski Gasket.

Is your triangular patch a fractal antenna ? Does your ~1% bandwidth exist only in the computer model, or with a real antenna ? Does your model include any loss at all ? Or is it a superconducting idealized fiction ? What does the model do if you add a -0.1 dB pad in series with the feed ?

Curiously yours,

J. Harvey, Ottawa

well bert
if it was me i would go with the antron A99 it is a cheaper and much better performing antenna and if you use it with a tuner you can use it on 10 12 15 17 meters with very good results below is a website with the antenna and its only about $40 for it
i have one and its only about 8 feet off the ground and i have worked about 40 countries with it on 10 meters alone
http://www.copper.com/product_menu.shtml

good luck

Huh? I'm a bit confused here. I thought the antenna was at 1/8 wave high??? Why would the radials be in the garden where the veggies should be? Heck, no wonder it didn't work... Oh well...Good gardening. I still have my 32 ft antenna, but it hasn't been up in quite a while. I took it down one summer when we were having extra heavy lightning nearly every day. I was paranoid about having a 70 foot lightning rod next to me. This winter would have been good, but I didn't use it. Now it's almost summer again...Mine also worked 17m as a 5/8 wave. Worked better than any of my other antennas on that band. I used an antenna mounted 24 volt relay to switch bands. When I went to 40m, I'd plug in the 24v transformer here in the shack. That would bypass the loading coil.MK

Dude... We Texans run realï¿½ full size antennas that radiate. If I ran
an EH antenna on 75m, I'd have to open my eyes to read morse sent by
flashlight. I wouldn't be able to make a decent qso otherwise. And if
a tall building is in the way...:(
>
> Hoping you will start to discuss with some good italian experimenters (not
> warming chairs only) soon, I wish you all the best.

I could do it maybe if I changed my name to Markano, but you all will
have to pay for the plane fair and temp visa, etc. I like italian food
so I could probably hang there for a little while anyway. I could
teach you all how to cook enchiladas as special bonus. I have to have
those on a regular basis to function properly. I doubt italians make a
good enchilada. Kinda like trying to find one in NYC. Their idea of
hot sauce is ketchup. Too scary to even think about. Almost as scary
as an antenna that looks like a UFO and has delusions of grandeur. But
don't feel too bad. You sure ain't the first on the block with a
"wonderstick" that defies all normal logic. MK

AEA used to make one of those. I think they used a fairly simple
loaded whip about like what you would see on a CB walkie talkie. You
would be better of putting up an outside ground plane or whatever and
feeding coax from the radio to the antenna. MK

5367. Screwdriver antenna matching

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-20 08:29:57 UTC

I am rather new to the screwdriver antenna. I have spent most of my ham life with vhf yagis and quads. I recently got a used screwdriver at a hamfest. The guy I got it from gave me two boxes and told me how to hook them up. He said that he knew that one of them wouldn't work, but couldn't remember which one. I got one of them sort of working. With a 5 ft whip on top I was able to get it on 10 meters ok. And to go from 10 meter to 15 metes it only takes about 1/2 inch more coil. And you can forget 20 metes completly. It is ok on 40 and 80 meters. But it is very touchy, especilly on 80. I

I would like the group's opinion on the matching of screwdriver antennas. How much coil? What material, torroid or air? How many turns and what size wire..

Hi to everyone,
I made several different EH samples and I use it for my radio activity on 40 m. I found it as a good dipole.
I can say that is good to construct it and to tune it (not alway easy!) but I see my log.

I'm in radio fron 1970, I'm always a QRP op, and homebewer, and not involved in EH business, I'm just an Ham.

The firt QRP contact I made was FROM INSIDE MY HOME with HA5KDQ with a power of 2 W in CW in 7 MHz with a 40 cm long antenna!!!!! It was worderfull and crazy!!!!! This was at sept. 29 of 2001.

This is what I see with my experience.
I don't know why, but it's in my log....

They are ok. Typical half wave as far as performance. They can cover a
wide frequency range with the gamma loop tuning and the ability to
adjust the tubing length. It's easy to remeasure the radiator to a new
freq and then adjust the gamma loop for best match. They also can be
converted to other types of antennas. I've made 5/8 wave GP's from
them by adding a bit more tubing and using a loading coil instead of
the gamma loop. Actually, you could even use the gamma loop to tune a
5/8 I think. They can also be further improved with an extra
decoupling section below the antenna. I used a set of radials 1/4 wave
below the feedpoint. The radials are grounded to the mast. This
reduces the feedline radiation and it's unwanted upward skewing of the
pattern. But they work ok even without the radials. I've got a
homebrew version I use on 10m at 20 ft with no decoupling, and it's
ok. MK

dear Paolo P
there are two possibilities:
1) is true
2) is not

50% and 50%.
are you so sure to be in the right part?
Please ask about the eh antenna to those many italian hams that are
successfully using it.
In USA they don't have the evidence yet, but in Italy there are many
evidences.
Why are you closing your eyes?
The antenna is speaking it's self, I repeat when well built and well tuned a
1% wav EH is equalling a full size dipole.

> ok. MK

I don't know if C-C calls the matching a gamma loop or ont but that is not what it is. It is a parallel L-C
circuit- one end connected (Hi impedance) conected to the bottom of the half wave (hi Z) and the other end
grounded. The inductor (loop) is then tapped up from ground until a 50 Ohm match is found. The coaxial stub is
the C in the L-C.
A gamma match uses a series C to cancel out the arm inductance of the match.

You are better off with any of the more modern horizontal omnis- lighter and in some cases more BW. The AEA halo radiated as much from the coax as it did the loop.

Thanks. That makes sense.

One more question pertaining to really high frequency stuff (800+MHz). I see antennas which use 1" square aluminum tubing as the boom. Elements at these freqs are only a few inches long. Construction was done by piercing the tubing, inserting insulators in the holes and running the elements thru the insulators. A VOM confirms DC isolation from the boom. Now the question: is that inch or so of element which is inside of the grounded boom "contributing" to the process, or is it "hidden" from the propagation process? At lower freqs, I'd expect that this doesn't matter, but in this scenario, we're talking about 25% of the element length.

Again, TIA!

Stefano,
just two notes,

a) I suppose it is not wise to presume 50 % probability when no proofs
are given, on this way I would be glad to persuade my bank that I am a
50 % billionaire and ask them for half a billion (my 50 % probability)
long term loan :-)))
b) I believe there is a quite large scepticism toward this antenna in
Italy, this doesn't mean that people believe the antenna doesn't work
but independent tests and proofs (not adverstising) are
required.

If you can't find one, try the PAR Electronics omni. Works great. I use one for rover operation...light, disassembles quickly and seems to work much better than the whip I had been using (subjective here). For contact info, do a google search for par and antenna or omni.

Cheers;

The vertical was first a ground mounted version with 8 buried radials
a little over a year ago. When that didn't work, I elevated it 20ft with
8 elevated radials. I couldn't tell any difference in the performance,
actually lack of performance. I couldn't rototill my garden last year
because of the ground radials. I tried each version for about six months.
If I ever mention trying a vertical again, someone please have me committed.

5383. R: EH Antenna: any news ?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-20 17:42:56 UTC
From: Alessandro Santucci I0SKK <i0skk@qsl.net>
Message-ID: <vV3m8.48536$1S3.1453663@twister1.libero.it>
Source record: 146421

OK hi tu everybody and sorry for may English, maybe I'm not so good but the important is what I can write here: I want to say to evryone my EH antenna experience.

In last september occasionally I saw the web site of Arno elettronica, Ted Hart site and all the EH antenna news. I tried to make one sample and aslo if it was quite different in measures from the Stefano IK5IIR model, it was amazing that was a good antenna: In fact I made a 40 CM long sample and make several QSO with 2 W of power, from INSIDE my home in 40 m evening. The antenna was on a woodeen support. I received 569 to 579 reports in a night! Wow!
So I decide to make the right sample, tyhe sample I found on Stefano web site. I told about this antenna to two friends of mine: IK0CPS Mauro, and IZ7DJR, Nino. We all are since 70's year in radio and wer excited by a 50 cm long antenna for 40 m!
We made a new sample, and Nino made three of them, and more made also a modified one, calling it "zippiro" (llok for at Nino web site on QSL.NET!).
We made a lot of comparison: we made comparison with a 20m long dipole on a 7 m mast. We mount the dipole and in a second time the EH, we mounted the two antennas toghether and found always the same result; the EH was of same perormance of the dipole on distance over the 1000 km.
We made also several test in several days on direct wave, as Mauro's location is abt 6-8 km far from Rome. We use two different receiver without AGC, and I measure abt 2-3 dB in favour of EH in different time of the day (mornign and evening).
I don't know wha but this "strange pipe EH" does function well. I think it's like a good dipole, but is just 50 cm long! Maybe it is capable to make my house radiating, maybe it is able to make all metallic object in my roof radiating, I don't know but it's able to do some good DX in QRP on 40 m.
We decided to make the test in 40 m as we think that in Europe is very hard to do QSO with 2 W only, as we had a lot of noise in that band, as in 20m 15m and 10m maybe it's possible to make contacts also with a dummy load(!!!....)
Anyway Nino IZ7DJR made a lot of DX and repeated them and passed in several pile ups with just 30 W of power alway in 40 m.

More, Pino IW0BZD is going to do a great number of experiment in VHF, from 50 MHz to up! He made different test with dipole, Jpole and I heard the EH is superior. I don't know why, but it's so!...

I'd like if several good hams can make test, optimizing this antenna, as a lot of programmers made on Linux system, some years ago, as I think it would be very good for us to have a good dipole for low bands to make inside a rucksuck and go on mountain!... hi.

It would be interesting to do test with different shapes, array, ad so on.
But it would be interesting to see the tests of many of us, not only 3 or 4
peoples in tha world, there are a lot of good engineer between us!

We wrote three articles on italian "Radio Kit Elettronica" magazine, after
we did the tests, and we are going to further investigate in this new tipe
of radiating element!

Hope to meet people that want to do QSO with EH, in different world parts.
I'll ba glad to write emails about serious tests, but sorry I'll not a
disposal for wars about EH antenna.
I'm not involved in Arno Elettronica or Ted Hart business, I'm omly
interested in radio, in tests, in order to learn, study and understand, and
at finish in QSO's in QRP, as I'm in radi since 1970 and always with home
made RTX!

All the best to everyone.

Hi Alex,

Sorry, but according to Stefano, it is highly unlikely that you did
any of this correctly. To determine the merit of what you did, can
you tell us:
1. How high above ground you have the EH mounted?
2. Do you use a 1:1 current balun as a choke?
3. Do you use a coil of transmission line as a choke?
4. How much current is present on the outside of your transmission
line?
5. What are the rough outline dimensions of the EH antenna (how big a
box would it fill)?
6. How many dB below a standard Dipole does the noise at the receiver
appear to be?
7. How many dB below a standard Dipole do your contacts hear your
transmission (DX only)?
8. Can you make your model available for independent testing?

Please note that questions 6 & 7 require a full size dipole mounted at least 1/4 wavelength above earth for proper comparison. Further, that dipole must be remote from the EH (more than 3 wavelengths away). If you cannot provide suitable answers, then I must presume Stefano was right and you could not build a good example for comparison.

We must be cautious about just what an EH antenna is. Given Stefano's reports of extreme difficulty to build this, it is apparent that anyone who reports otherwise has obviously NOT built the right antenna. Sorry, but you first have to prove you have an EH, not merely another radiating dummy load.

one other item to confirm in regard to question 5:
> I repeat when well built and well tuned a
>1% wav EH is equalling a full size dipole.
>73's Stefano
I overlooked your description of your antenna being 40 cm long; this
is about twice the size described by Stefano's 3 lines above and as
such obviously does not qualify as a true example, Sorry, but I for
one cannot accept (according to Stefano's descriptions and warnings
which you confirm) that you have built the correct model where the
errors in construction are significant and you did not tune it well.
This is consistent with Stefano's claims however.

Too bad :-(
1 testimonial up - 1 testimonial down. Hardly worth it, and a far cry
from:
>many italians hams to report here their
>SUCCESSFULLY experiments with eh antenna.
Many? Not even one in these 6 or more months? Too bad this EH is so
difficult to build, tune, and test. If I am to understand Stefano,
many have tried and only your erroneous report has appeared.

Thank you anyway.

>if it was quite different in measures from the Stefano IK5IIR model

Again we are faced with what is NOT an EH antenna when Stefano has
made it clear that
>I repeat when well built and well tuned a
>1% wav EH is equalling a full size dipole.

And you go on to build it even larger:
> I made a 40 CM long sample and make
>several QSO with 2 W of power, from INSIDE my home in 40 m evening
or:
> a 50 cm long antenna for 40 m!
>I think it's
>like a good dipole, but is just 50 cm long! Maybe it is capable to make my
>house radiating, maybe it is able to make all metallic object in my roof
>radiating, I don't know

OK, so the EH has grown another 25% and the experimentor/tester is at
a loss to describe how it works (very common problem apparently):
>maybe it's possible to make contacts also with a dummy
>load(!!!....)

Well, that IS a comparison that we have long suspected as being
accurate, thanks!

>72/73 de
>
>Alex I0SKK/QRP

Hi Alex,

Same report with spurious data, but with even more obvious problems.
It is more than apparent you did NOT conform to the EH dimensions as
described by Stefano, and you went even further to make changes of
your own. You show the proper skepticism, that is good; and you show
an inclination to improve the design (who would have thought that
possible - or necessary? Didn't work very well the first time, hmm?).

The single greatest improvement is that you at least test your design.
This is something that Stefano has not been successful at for many,
many months (wonder why?). However, you say nothing of using a choke
at the feedpoint, nor do you measure transmission line currents, nor
do you say how high the EH (sic) was elevated above ground.

Sorry, without such details, your report is just a vague collection of irrelevant data. Thanks for trying anyway.

The count remains at one up, one down.

> I do not know how the size of the 450 compares to the 800sdx. But ...
>
> I had to remove one diagonal to get a Yaesu 450 in to my Rohn 25.

????!! I did not. I have the YAESU G-450-XL installed mid-way
in the top section of my Rohn 25 tower. I home-brewed the base
mounting plate -- which needs shims on at least one of the
horizontal's to make it level. I agree with the YAESU-bolts-
are-too-short observation. YAESU must've designed it to be
installed on a pie tin.

I did find that the 450 expected to twist a far larger diameter
mast than the top section of the Rohn 25 could swallow. This
results in an off-center rotation of the mast (if uncorrected)
when using a mast that the top sleeve _can_ accept, and can/did
cause binding. I solved *that problem* by using thickish metal
shim plates in the rotator-to-mast clamping assy.
It's been doing ok for several years now.

5391. Rookie needs help with impedance matching a ferrite antenna w/ reciever

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-20 19:38:15 UTC
From: stephendeese@hotmail.com
Message-ID: <25cad608.0203201138.36569108@posting.google.com>
Source record: 146429

My Goal is to design a better ferrite antenna for my WWVB 60khz
circuit. I have an antenna which I took out of a Radio Shach clock.
It is pretty good.

I intend to incrase the sensitivity by increasing the cross sectional
area of the ferrite rod and by increasing the Q (sensitivity = Efield
* He * Qload where He is a function of cross sectional area).

I realize that to get maximum performance, I need to create an
impedance matching circuit to go between the antenna and the reciever.

so...

1) How do I determine the impendance of the reciever IC that I am
using? The application guide for the IC says that the impedance is
approx. 2Mohms. Should I take it that the impedance of the reciever
IC is all resistive (with no reactance) ??

2) The antenna is basically a parallel resonant circuit with values
for L, C and R. R is not easy to calculate because it involves core
losses. Could it be measured directly using a multimeter?

Once I know the answer to these two questions, I should be able to
come up with an impedance matching circuit.

In the end I hope to increase the Area and Ql of the antenna.... then
add an impedance matching circuit .... resulting in a much better
signal.

Does this seem like the right approach?

Thanks for ANY help!

May Christ richly bless you in every way
Stephen

Source record: 146432

OK Rich,
I'll try to answer, but I don't have the aim to convince you, so if you want can make your sample, anyway, and I think you'll be more able to make agood sample.
However about the mine it is in my location and I have three samples, the first one, the right one (with the right measures, and that I used for tests, and the "zippiro" the model that my friend Nino IZ7DJR made) and anyone can come here in order to use and test, no problem at all.

When I made the first test the antenna was mounted on my wife's broom..... at 1 meter height!
Than the right sample (with measure according to Stefano model) was mounted at 7 meters or 8 meters over the roof.
The same height was the apex of dipole we used for comparison.

When I measured in direct wave I measured by 2 to Ther dB in favour of EH, and I think that according with an error of 2 dB, can say that the two antennas were equal in perfomance.

I used two different power level, 2 W out from TX, and 5 W out from TX.
I didn't measure current, I used the same power for the two antenas, dipole and EH.
I didn't measure the roof dimension. The DX station gave me the same result with EH and dipole.

OK I know the dipole is not in an optimum installation. But I've not to cerify any antenna, I have just the need to undertsna dif the EH can be used as antenna, and for my opinion is ok. I repeat I'm not involved in any business, I don't have any desider to convice anyone. My friends Mauro IK0CPS and Nino IZ7DJR, and Pino IW0BZD used other EH samples and we are happy of these. We enjoy radio, we are not business man in this fiedl so anyone can make test good test, real good test, but no one is forced to do so, and I think it's real good side of our hobby.
I think it's not usefull to spend time to write messaghe, it's better to transmit or to construct devices. If you are interested make you own antenna, is you are not inerested don't do so: that's all. This is my simple opinion, sorry!
Anyway I think that can be usefull for everyone to know that exists and antenna like the EH and the possibility to copy it and to do by himself a sample. But really no one must do so.
Thanks for attention.

This is the last answer I do, as I don't use to download the NG news, so if you need, can you send me emails and I'll be glad to answer directly. Sorry but I don't like to be in disagreement with anyone! I'm not perfect... hi!
Bye.

Ralph Mowery did a pretty good job of explaining things but I thought
I would just add a little more.

You won't notice the differences in the antennas by just reading the
specs, unless the specs listed the number of elements, the element
spacing and the lengths of all the elements. With this information you
would have noticed that the elements for the antennas with non-insulated
elements are slightly longer than a corresponding element of a antenna
with insulated elements. If two antennas have the same number of elements
and the element spacing was about the same, they are going to have
specifications that are very close to one another.

The type of Boom, metalic or non-metalic, and the method of mounting
the elements effects the length of the antenna array elements.
Close proximity of a metalic boom to the antenna array elements
causes a shortening effect which raises it's operating frequency.
Lowering the operating frequency back to the design frequency would
require the elements to be lengthened. If the elements are actually
bonded to the metalic boom, as opposed to being insulated from the
boom by grommets, even more of an effect is realized. The precise
amount, to lengthen the elements by, is based on the design frequency
and the relationship of the Boom Diameter to the design frequency,
in Wavelength.

The difference factor is called the Boom Correction. The Boom Correction
for antennas with metalic booms where the elements are insulated, but
pass through the boom, is approximately 1/2 the Boom Correction applied

to an antenna where the elements are bonded to the boom.

As a side note, if you space the elements above or below a metalic boom on insulators such that the metal-to-metal spacing is greater than the boom radius, no Boom Correction is necessary.

More detail on this phenomenon can be had by consulting the ARRL Handbook. A very nice program, written in Basic by Gunter Hoch, DL6WU, can be obtained on the internet that is intended for designing VHF/UHF Yagis. The program takes into account the type of boom and the boom-to-element mounting. The output of the program is a antenna design that lists the element spacing and element lengths. It's relatively easy to change the boom-to-element mounting and see the difference it makes in the element lengths.

Just do a Yahoo search on "DL6WU" and you will get a bunch of hits that lead to a copy of the program source. Off hand, I don't remember where I obtained my copy.

If you are interested, I did a conversion of this program into a web page that is HTML/JavaScript driven. I don't have it out on a web site but I can send you the sources. It's not very big, ~150 KByes.

My next antenna is going to be an end fed zepp for 40M. My question is, how long does the twinlead have to be and can I put a balun on the end of that and run coax into my house? Any thoughts?

> ...yet.
> Icom 710, to be installed.

An Icom 710 is a nice rig. I have one on board as well as a Kenwood TS-50. If Harbour Control states to change to channel 849, it is 8-4-9-enter on the M710 vs consult a listing of frequencies for the ITU channel designations, select VFO A, dial up the receive freq, select VFO B, dial up the transmit freq, select VFO A, select SPLIT FREQ, and finally select Freq Lock on the Kenwood. What would rather do in an emergency???

ICOM creates a lot of marketing hype about the M710 being a 150 Watt radio. It is, 150 W PEP on SSB just like the TS-50. It is also 100 W on CW, RTTY or PACTOR just like the TS-50. The watt meter settled the power issue definitively.

I use an SGC SG230 auto tuner feeding the back stay as a delta loop formed by the back stay, the mast, and 1 inch tinned copper braid leading back toward the SG230 in the lazarette. The delta loop configuration does not require expensive and failure prone back stay insulators. It is a closed loop which presents less receiver noise and is more balanced than a back stay working against a ground. Tinned copper braid can be found at commercial electical suppliers.

I have assisted in many installations using just a random wire hoisted with a flag halyard. IMHO this is preferable to the back stay insulator route. However with a random wire or back stay, the counterpoise is critical.

If you have a metal toe rail, wire the toe rail, both port and starboard, to the ground point on the tuner. Our toe rails are wood.

I have a 100 sq ft ground plate and the delta return loop attaches to the ground plate enroute to the auto tuner. The ground plate forms the lightening protection for the mast.

I run tuned twin lead radials (see the Butternut website for measurements) port and starboard from the tuner forward.

The engine is grounded to the ground plate. The stanchions bases are bonded (tied) together and attached to the tuner ground. Thus the

engine mass and the life lines + bow/stern pulpit are used as a counterpoise.

The more counterpoise you have, the better the capacitive coupling to sea water and the better your above the water antenna tuner combo functions. I cannot emphasize the more counterpoise you can codger together, the better the whole thing will work.

We have not needed to lay copper foil as is common practice with a random wire or back stay antenna.

The tuners can be purchased through SGC, http://www.sgcworld.com, or the ICOM tuner through your ICOM dealer. West Marine sells copper foil as well as the ICOM radio and ICOM tuners.

A roll of copper roof flashing from your local building supplier is less expensive than the West copper foil. It all tunes green anyway in the salt environment.

One has to love the no hassle return policy that West has. If you don't like it (because it broke or did not do the job) you can return it for a full refund including sales tax. If you buy from your trusty ICOM dealer and it breaks out of warrantee or does not do the job, you own it. I had an expensive inverter fail after 4 years. It only had a 6 month factory warrantee. West gave me a full refund.

If you transit the Panama Canal, you can source ICOM items inexpensively at the Duty Free Zone near Colon on the Atlantic side of the canal. I would prefer to deal with West, http://www.westmarine.com.

An end-fed Zepp is 1/2WL (about 66 ft. on 40m). It is fed with 1/4WL of
open-wire line (or ladder-line). That's about 31 ft. of 450 ohm ladder-
line. IMO, you would be better off with a balanced antenna.

OK, so you do not intend to convince - a self fulfilling prophecy. As
for making a good example, you and Stefano do not seem to agree on
what exactly that is; why should I have to guess when neither of you
seem to be able to perform such a simple task? Don't you guys have an
expert in this who can discuss these things?

>However about the mine it is in my location and I have three samples, the
>first one, the right one (with the right measures, and that I used for
>tests, and the "zippiro" the model that my friend Nino IZ7DJR made) and
>anyone can come here in order to use and test, no problem at all.
>
>When I made the first test the antenna was mounted on my wife's broom......
>at 1 meter height!

You once again neglect to provide the distance above earth in this
regard. Which floor is your apartment on?

>Than the right sample (with measure according to Stefano model) was mounted
>at 7 meters or 8 meters over the roof.
>The same height was the apex of dipole we used for comparison.

Still no discussion of the usage of choking in any form. In fact, the
subject seems to be entirely evaded.

What is even more strange is that you elevated the EH 7 or 8 meters
OVER the roof. How tall is your apartment building? Why elevate it
all? According to your Gurus, this antenna is not affected by ground.
This is supposedly for the purpose of comparison to a dipole? None of
us will accept that as valid. The EH claims to be ground independent
and that means that you test it from ground level - not in the air. I
would offer there is a very simple test for this, but you have
announced you are not interested in the technical issues :-(

There is nothing in your response to indicate that both the EH and the
Dipole did not have radiating transmission lines of far greater length
than 1% claimed. In fact, this is the source of positive results you
have observed. It fools many non-critical observers who are happy for
any results. You only convince us that you are gullible.

You will note that none of these objections is based upon "opinion"
(except for being gullible - I suppose there are other, less
opinionated qualifiers that amount to the same thing).

>
>When I measured in direct wave I measured by 2 to Ther dB in favour of EH,

It is very difficult to measure accurately to 2dB on the average Ham
radio. Would you care to reveal how this increase in accuracy is
achieved?

You will note that this objection is not based upon "opinion."

>
>I used two different power level, 2 W out from TX, and 5 W out from TX.
>I didn't measure current,

Why not? This retains the evasion from the principle form of failure
for this model of antenna.

You will note that this objection is not based upon "opinion."

> I used the same power for the two antenas, dipole
>and EH.
>I didn't measure the roof dimension. The DX station gave me the same result

>opinion, sorry!

OK, your opinion is just that, and not to be confused with science, technical accuracy, or validation.

It is not an issue of me making an EH, it is an issue of yours or Stefano's operating at all. You have suggested that you are not interested in accurate measurements, unfortunately your opinion does not have much to offer, especially when you show every inclination to bail out.

>Anyway I think that can be usefull for everyone to know that exists and

> Alex I0SKK
>

Hi Alex,

No answers to my specific questions I take it. This is a familiar lack of response for the EH/CFA/fractal topic in spite of their being fundamental and simple enquiries. Still and all, it does show your and Stefano's inability to take part in a technical discussion.

One lonesome, embarrasing testimonial up, one lonesome, embarrasing testimonial down. You must agree that the EH group does not present themselves as a very coherent nor a very technical crowd.

Sorry, but it still appears that the EH community cannot produce a single working EH for independent testing, and has failed consistently for more than 6 months.

You list several of your friends who have performed construction and use of this design. Have they enough technical understanding to report fully, and to respond faithfully to technical issues? You claim you are not that person; Stefano has clearly shown he is incapable; and both of you act like it is of no consequence. I am sure you will understand that we are not very interested in naive opinions such as what the two of you have offered.

Is EH just as good on receive as it is on transmit ?

If "reciprocity" works with EH antennas there's no need to make any transmission test prove how good they are. That should speed things up quite a bit.

Please publish results of this longest-running cliff-hanger ever in the next hour. It will soon be my bedtime.

Of course, a ground mount with 8 radials is not going to be a
barnburner. But neither will one at 1/8 wave with 8 radials.I could
have told you that before you started. I don't really like ground
mount verticals unless there is no other choice.

I couldn't tell any difference in the performance,
> actually lack of performance.

The elevated should have been slightly better. But still not optimum
by any means.

I couldn't rototill my garden last year
> because of the ground radials. I tried each version for about six months.
> If I ever mention trying a vertical again, someone please have me committed.

Well ok. It's a shame you couldn't have tried one with the proper
number of radials for good performance though. That would be like me
testing a dipole, but only allowing it to lay within 2 ft of the
ground and then wondering why I wasn't really doing too hot to dx.
Mine worked so well going back to the dipole was a real letdown. I
don't work much 40m at night lately as a result. I've also heard of
others that had the same results, so I know it's not just me. I just
hope you don't really believe you made an accurate comparison between
the two types of antennas. You didn't. You minimized the most
important part of the vertical. I think to have a really fair test, if
the dipole is at 40 ft, the base of the ground plane should be also,
with at least a decent amount of radials. That puts each antenna's
points of max current at about the same height. When I say decent, I
mean at least the equal of 60 on the ground for a starter kit. Thats
how I made my test, and the vertical ate the dipole for lunch to dx.
Oh well... You have more room to grow lunch now. :) MK

5407. cable routing in an auto

Message-ID: <8dbi9u4ldegf2boia4oa6i0rckenq6b9dc@4ax.com>
Source record: 146444

I'd like to start a discussion on routing the antenna cable in an auto. I'm looking at an antenna (for 2m) mounted near the rear of the vehicle, and I've come up with two ways to run the cable.

First, I thought about running it into the trunk, then up through the interior, hiding it behind door trim , across the bottom of the dash to the transceiver. But lately I've been thinking it would be far easier to run the cable under the car, up into the engine compartment and through the firewall.

I have considered putting the antenna up front and running through the firewall to it, but I think it will look awfully strange.

Any thoughts? Thanks.

==========
Cecil.

Did you retune the LENGTH radials of the radials when you elevated them ?

It's an absolutely vital question !

And did you do the corresponding operation when checking with Eznec ?

Reg.

The oceanfront property in Little Rock AR. still has your name on it. I stood on it's long winding drive just last week and caught a large halibut from a 38 year old septic tank using nothing but a 10m hamstick, about 30 ft of thin string, and a piece of rank cheese. I was just plain amazed. So I can relate to how you must feel in your quest for the ultimate wonderstick. 73, Markano

Or maybe I should rename myself Markoni? That has a better ring to it...More radioish sounding...

5410. Re: Dipoles Vs Verticals

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-21 01:49:53 UTC
From: Roy Lewallen <w7el@eznec.com>
Message-ID: <3C993C41.218FBCAB@eznec.com>
Source record: 146447

Energy leaves your antenna by two propagation means, which are very different from each other.

One is the ground wave. Energy propagated by ground wave follows the contour of the ground. Only vertically polarized waves propagate by this means. The ground wave signal is attenuated quite rapidly with distance from the source, much more rapidly than the inverse of the distance (for field strength) or square of the inverse of distance (for power density) than is the rule for the sky wave. The attenuation is greater as the frequency increases, so in the middle of the HF range, communication of only a few miles is possible using the ground wave. The question was asked if the ground wave fizzles out and doesn't reach the ionosphere. The answer to this is yes. If fact, it never even goes in the direction of the ionosphere -- a wave launched straight out horizontally and propagating by ground wave follows the curvature of the Earth. At higher angles, the ground wave fades out even more quickly than horizontally launched waves. Ground wave is the primary propagation mode for AM radio broadcasting during the daytime, and for lower frequency stations like WWVB (60 kHz). Because of its rapid attenuation with distance, it's not of much use at HF except for local contacts. You'll find more information on ground wave propagation in the ARRL Handbook and Antenna Book.

The other means of propagation is the sky wave. Signals propagting by this means are attenuated only because of their spreading out, so the field strength decreases inversely with the distance, and the power density as the square of the inverse of the distance. This is the propagation means by which all HF communications of more than a few miles are made. At HF, beyond a few miles only the sky wave remains due to the rapid attenuation of the ground wave. The sky wave includes energy propagating directly from the antenna and energy which has reflected or refracted off the ground after leaving the antenna. These direct and reflected rays sum together to create a pattern that differs according to the antenna height. Although horizontally and vertically polarized signals react differently to reflection from the ground, both polarizations are propagated by sky wave.

A single antenna pattern can be drawn that will give the shape of the ground wave signal at all distances from the source, because the attenuation is the same for all parts of the pattern. This isn't true for ground wave signals, so if a pattern is drawn of the ground wave signal alone or a total signal including both ground and sky wave, the distance from the source has to be given. The pattern will have a different shape at each distance.

The standard and demo versions of EZNEC plot only the sky wave as its
far field output. This is the signal that exists at all distances beyond
a few miles at HF, or perhaps a few tens of miles at MF. If ground wave
amplitude is desired, you can use the near field analysis, since the
"near field" analysis is actually the complete field, near or far.

There's no fixed correlation between the sky wave at low angles and the
ground wave, except that if a change is made in antenna efficiency, the
ground and sky waves are affected the same amount. But you can't
determine what the ground wave is by looking at the sky wave field
strength at any elevation angle. Again, if you do want to determine the
ground wave amplitude (actually, the total field strength regardless of
propagation mode) with EZNEC, use the near field analysis.

Roy Lewallen, W7EL

If I'm reading the depiction's right from the antenna book, the boom is
located at the neutral point of the sign wave that travels out from the
feed point of the dipole elements (center) The Reflector and Director(s)
have the same potential electrically by inductance and wouldn't need to
be isolated form each other. Sound right Doc/ Cam? Guess we better not
get into LOG booms, huh? :-)

If the EH antenna is able to work on 160 metres (and that is what we are told) it must also work on 1500 kHz as well.

Yes, and properly scaled, on 10 m, too.

Why not test the EH antenna at 10 m?

Erect a 10 m ground plane as a reference antenna. 100 metres away erect an EH. Bring the feedlines to a more or less central point for a / b switching to compare the antennas. As Reg noted, reception is test enough.

Unless the EH triumphs, its promoters will likely fault he results. I have experience with such a competiton with measurement transducers. We offered suppliers an opportunity to siubmit one sample of a production transducer for a competitive evaluation we would sponsor. We were going to buy at least hundreds of items from the winner of the competition. Every maker we ever heard of wanted to compete, and did. All the losers claimed their sample had been faulty or misapplied and asked for another chance. They all had the dog ate the homework stories to tell! We said, "Sorry, no second chances. We have a job to do now." The test winner`s transducers performed in the field as they had on test. We were happy and so were the suppliers.

Bill Seward, KG4SAQ wrote:
"Any thoughts (on antenna and cable placement in an automobile)?"

Yes. The best antenna location is the center of the roof, but most users don`t want it there. Ahead of the rear deck lid, and off to the side, works for most users. It`s not in the way physically or visually.

The cable should be routed beneath the rear seat and floor mats all the way to the firewall where it emerges from beneath the mat and is routed to the radio. The cable is fully protected, out of the way, and unobtrusive.

Removal of the door thresholds on one side of the car, and the rear seat, makes the cable routing easy.

Best regards, Richard Harrison, KB5WZI

You can't buy them! You have to earn them!

One fellow arrived at the Pearly Gates and was met by St.
Peter who
asked him to relate something nice he had done for someone.
The chap told St. Peter that he had encountered some Hell's
Anglels
punks bothering a young lady and told them to back off.
"That's nice," said St. Peter, "and when was that?"
"About two minutes ago!" replied the chap!

A vertical simply requires too much overhead for good results - 30 times
as much wire as a dipole, higher than a dipole, and much more of an eyesore
than a dipole. I put in 50 times as much work on the vertical as I did
on the dipole.

Roy Lewallen wrote:
"Ground wave is the primary propagation mode for AM radio broadcasting during the daytime and for lower frequency stations like WWVB (60 kHz)."

Yes, and ground wave does not fade away at night. It is the primary propagation mode for AM radio broadcasting during the nighttime, too. Sky wave is a nuisance at night to the medium wave broadcaster because it curtails his ground wave reception by destructive interference with the ground wave at the point, and beyond, where the sky wave skip zone ends.

Roy also wrote:
"Because of its rapid attenuation with distance, it`s (the ground wave) not of much use at HF except for local contacts."

Very true, but the value of local contacts should not be minimized. The locale can be enormous.

The ground wave is conveniently divided into two components, a surface wave and a space wave (says Terman). The surface wave is not good for much at frequencies higher than those used for medium wave brodcasting. But, space waves are used for land and mobile communications, including CB, FM and TV broadcasting, microwave relay, communications into the far reaches of space, etc.

Best regards, Richard Harrison, KB5WZI

AEA is no longer in business (at least in making antenna's) so the
odds of finding one new are quite slim. There are other options
though, as mentioned PAR has an omni 'triangle'; also you might look
into KB6KQ loops at http://www.kb6kq.com/index.html have spoken with
guys using them and they get out okay. I have an AEA that I use when
portable, it works - but if I had to do it over I'd go for a PAR or
KB6KQ as they seem better suited to transport (better 'profile' and no
ceramic insulators to break).

Ya think the pics are cool, you should drop by his shop sometime.

Always helpful, has good ideas - some AMAZING 'home brewed' fabricatin
tools - and even a not so bad cuppa coffee. Better yet - seems he always
has time to show an interested ham around and answer what have to be
familiar questions over and over again.

I've had pleasure of visit'n Al's shop a couple times. He's always been
more interested in getting another ham on the air, better equipped,
ideas shared or more informed than in simply make'n a buck. He listens
too. Want's to know how folks are use'n stuff - what can be done to make
it better. Wether he built it origionaly or not.

You got an idea? He'd like to hear it.

Amateur Radio Newsline Report 1283 – March 15, 2002

Amateur Radio Newsline report number 1283 with a release date of Friday, March 15th, 2002 to follow in 5-4-3-2-1.

The following is a Q-S-T.

Restructuring at the FCC should not impact on Amateur Radio and a first for the Dayton Hamvention. These stories are first on Amateur Radio Newsline report number 1283 coming your way right now.

(Billboard Cart Here)

**

REGULATORY ISSUES : FCC REORGANIZES LATER THIS MONTH

A reorganization of the Federal Communications Commission is set to become final later this month. This, as the agency stresses that realignment of responsibilities between various bureaus will make it more efficient and help it better respond to a changing technological marketplace. Amateur Radio Newsline’s David Black, KB4KCH, takes a look at some of the changes.

--
It’s an independent government agency that reports directly to Congress. It’s mission is to regulate communications. One of the services it oversees is Amateur Radio, but most observers of the reorganization of the Federal Communications Commission see little impact on hobby communications.

As part of the reorganization a new Media Bureau will combine the duties of the current Cable and Mass Media bureaus. The goal of the combined bureau? To treat competitors of multiple entertainment delivery systems equally and consistently. This includes broadcasters, cable operators and satellite service providers to name only a few.

Other changes include a renamed Consumer and Governmental Affairs Bureau. Also, a realigned International Bureau still will handle satellite licensing but most policy issues will now be the domain of the newly created Media Bureau.

These are just a few of many changes taking place. Most appear aimed at commercial interests. For ham radio, C-B, G-M-R-S and most two-way radio users the shift will probably be transparent. In other words, for these spectrum users and most others, it looks like business as usual within a soon to be restructured FCC.

From the South-East Bureau in Birmingham Alabama, I’m David Black, KB4KCH, reporting for the Amateur Radio Newsline. Don.

--

Congress endorsed the plan late last year. The FCC then approved the overhaul in January. The changes will take effect March 25th. You can read more on the web at www.fcc.gov. (ARNewsline (tm) from published news reports)

**

RADIO LAW: FCC REFUSES TO SIDE WITH CB'ER IN LOCAL CITATION CASE

The FCC has refused to hear an appeal by an Illinois C-B operator who was convicted of Disorderly Conduct for using an 11 meter Class D Citizens Band Radio. Amateur Radio Newsline's Norm Seeley, KI7UP, has the details:

--
Gary D. White is among the first C-B operators dinged under a new authority granted by the Federal Government to states and municipal law enforcement agencies. Authority to control interference caused by operators of Class D 11 Meter C-B radio sets.

White was convicted on a state Disorderly Conduct charge of operating his C-B equipment in an unreasonably loud, offensive, harassing or threatening manner. He was not convicted of violating any FCC rules. White believed that the citation was based on interference to a neighbors telephone and television receiver. This in itself is not a violation of FCC Part 95 rules. And because of this he also believed that local authorities had no justification to sanction him. So he appealed the conviction to the FCC.

But the FCC says that the proof of guilt on the Disorderly conduct allegation is not in its preview to consider. This is because no FCC rules were violated. Also, under a law enacted by Congress in November of 2000, state and local governments are free to enact laws to enforce existing Part 95 Citizens Radio Service rules.

Bottom line. The FCC will not interfere in the case and White will have to find other avenues if he wishes to continue his appeals.

For the Amateur Radio Newsline, I'm Norm Seeley, KI7UP.

--

Congress enacted the law to give state and local authorities enforcement authority over 11 meter C-B operators due to the rising tide of unnecessary and harmful interference to other people using radio devices in near-by spectrum. This includes corded and wireless telephones, television receivers, stereo Hi-Fi sets and other consumer electronic gear. Ham radio is specifically exempted from the law and any ordinance it may be used to create. (W5YI Report)

**

HAM RADIO RIGHTS: NM. AND W.VA. JOIN THE PRB-1 BANDWAGON

The ARRL Letter reports that New Mexico and West Virginia have become the 14th and 15th states to adopt pro Amateur Radio antenna bills based on the limited

federal preemption known as PRB-1. Amateur Radio Newsline’s Jeff Clark, K8JAC, reports:

We have this report:

--
In New Mexico Governor Gary Johnson signed House Bill 314 on March 5th. This, after it easily passed both houses of the legislature last month with just two opposing votes during a short session that typically only deals with appropriations bills. Called New Mexico's "Emergency Communication Preservation Act" the measure was sponsored by State Representative Mimi Stewart and Senator Ramsay Gorham. It stipulates that municipal or county ordinances regulating Amateur Radio antennas cannot obstruct or preclude amateur radio service communications. Also, that such ordinances shall reasonably accommodate amateur radio service communications.

Here in West Virginia Governor Bob Wise signed House Bill 4335 into law on March 7th. The bill provides that antenna structures may be erected at heights and dimensions sufficient to accommodate amateur radio service communications but does not include a minimum regulatory height schedule. The measure also exempts Amateur Radio antenna towers constructed prior to the effective date from subsequent zoning regulation changes.

From Charleston West Virginia, I’m Jeff Clark, K8JAC.

--

In signing the West Virginia bill into law, Governor Wise, whose late father held the call sign W-A-8-A-Y-P, also proclaimed March 7 as Amateur Radio Operators Appreciation Day across the state. (ARRL)

AMERICA AT WAR: NEW TERRORISM ALERT SYSTEM

The United States has a new color-coded terrorism warning system. It was revealed on Tuesday, March 12th by Homeland Security chief Tom Ridge.

The five-level system is a response to public complaints that broad terror alerts issued by the government since the Sept. 11 attacks raised alarm without providing useful guidance. The lowest-status warning is green, followed by blue, yellow, orange and red as the perceived dangers intensify.

As the terrorism warning system was unveiled, Ridge said that the nation is on yellow alert. This means that the United States is facing a significant risk

of danger but not the highest stage.

The alert system is in force immediately for federal agencies, and Ridge is urging state and local governments to adopt it, too. It will be subject to a 45-day comment period, after which it probably will be revised. It's not known what part if any Amateur Radio will play in the new enhanced terrorism alert scheme. (Published news reports)

**

ENFORCEMENT: TAKE THAT UNCOORDINATED REPEATER OFF THE AIR

The FCC has told the operator of an uncoordinated North Carolina repeater to stop interfering with a coordinated machine, even if it means immediately taking his system off the air. This is the edict handed down to the operators of the NY4X repeater by FCC Special Counsel for Amateur Radio Enforcement Riley Hollingsworth, K4ZDH.

--
Hollingsworth: " We also notified Richard Howell, NY4X, of Greer South Carolina and John Parker, AG4AZ, of Brevard Norrth Carolina that upon reciept of the letter, the NY4X repeater that they operate had to either shut down, obtain coordination or submit a detailed plan to the Commission to prevent interference to the KU4OL [repeater]."

"Now this interference has been going on for quite some time. We notified Parker and Howell back in November that something had to be done. Nothing was accomplished in regard to coordination and nothing was done in regard to the interference."
--

Hollingsworth letter says that Howell and Parker had more than ample time to fulfill their obligation under Section 97.205 of the Commission's rules. And late word is that the repeater has been shut down. (FCC, RAIN)

**

ENFORCEMENT: TAKE THAT BROKEN REPEATER OFF THE AIR

The NY4X repeater is not the only machine currently under FCC scrutiny. Another one is in Northern California. This one is having technical problems and is causing interference to machines on adjacent channel pairs. Again, the FCC's Riley Hollingsworth, K4ZDH:

--
Hollingsworth: "We notified Wendall Peterson of Walnut Creek California, operator of the K6POU repeater that more than enough time has elapsed for him to correct the technical and control problems with the repeater. His earlier response to our inquiry showed that the bandwidth was indeed so wide that it caused problems to two other repeaters. We have gotten complaints about that. And the repeater system is just not operating in accordance with good Amateur practice."
--

Hollingsworth says that his office expects the problems with the repeater to be corrected or that the machine will be taken off the air. He also gave Peterson 20 days from the date of his letter to respond. (FCC, RAIN)

**

ENFORCEMENT: THE RESPONSIBILITY OF REPEATER OWNERS

The FCC enforcement involving the NY4X and K-6POU repeaters are just the latest in a series of actions aimed at cleaning up the problems that have been plaguing the F-M community. Whether it's an uncoordinated repeater causing havoc to a coordinated machine, or a long established system in need of maintenance, the FCC's Hollingsworth says responsibility comes with repeater ownership:

--
Hollingsworth: "We want to emphasize that repeaters are voluntary. Nobody has to put one up. But if you do put one up you have a responsibility to maintain it, to get coordination if that's necessary, and to operate in accordance with good Amateur practices, especially if other repeaters are being detrimentally affected."
--

In reality, the only things the FCC is asking of those who own and operate repeaters is to be good neighbors and to adhere to the proper technical standards. In this way, the repeaters themselves can better serve their service area and the ham radio community in it. (FCC, RAIN)

**

RESCUE RADIO: KNOWING WHERE YOU ARE IN THE MID WEST

If you drive the highways and by-ways of Kentucky, you need never worry again about where you are. And if you get in a bind, rescuers will be able to find you. That is, if you are a ham radio operator equipped with a mobile APRS station. Jack Parker, W8ISH, of Amateur News Weekly, says that in his part of the world it is a mode that is truly coming of age:

--
Good news from the Kentuckey Automatic Position Reporting Society" their network of APRS digipeters is growing like well bred Kentucky Race Horses.

According to Brian Walker, KC4FIE, several new sites will be coming on line very soon. New digi's are planned for Grand Rivers, Morgantown, Owensboro, Lawrenceburg, and Dry Ridge to name a few.

The Murry State University club has added a digipeter and two stations along the Kentuckey – Tennessee border have extended APRS coverage into that state. These efforts effective extend the Mid-West network of APRS digipeters established by the Tri-State Working Group in Ohio, Indiana and Illinois.

If you need more information on the Automatic Position Reporting System just check the APRS Working Group website at www.tawg.org.

Reporting for Amateur News Weekly, this is Jack Parker, W8ISH.

--

With interest in A-P-R-S growing and ham gear that includes the mode as a standard feature, look for a defacto nationwide network to be in place by the end of the decade. (ANW)

**

HAMVENTION 2002: HAM TESTS WILL BE AT THE HARA

The Dayton Hamvention has asked that we pass along a correction to some information in its recently mailed pre-show brochure. The pamphlet incorrectly lists Meadowdale High School as the venue for Amateur Radio license exams. This is incorrect. The Hamvention says that all license exams will be held at the HARA Arena Hamvention site. (Hamvention(r))

**

HAMVENTION 2002: QCWA BANQUET

And attention QCWA members. This years annual banquet in conjunction with the Dayton Hamvention will be hosted by the South West Ohio chapter and will be held on Friday, May 17th. The venue is Alex's Continental Restaurant near Miamisburg. Starting time is 7:30 P.M. and reservations are required.

This years speaker will be General Raymond Moorman. He will be talking about the United States Air Force Museum and plans for the upcoming Centennial of Flight celebration in 2003. For more information and to make reservations please contact Ed Sonnanstine by e-mail to EdSonny@aol.com (QCWA)

**

CONVENTIONS - UTAH: UTAH HAMFEST

The 2002 Rocky Mountain Division ARRL Convention and 2002 Utah Hamfest will be held July 12th to the 14th at Ruby's Inn at Bryce, Utah. The venue is near Bryce Canyon National Park. For more information please visit www.utahhamfest.org on the world wide web. (Utah Hamfest)

**

CONFERENCES: ARRL/TAPR DIGITAL COMMUNICATIONS CONFERENCE

Technical papers are being solicited for presentation at the 21st Annual ARRL and TAPR Digital Communications Conference. The event will be held this September in Denver, Colorado. Presentations will also be publicized in the Conference Proceedings. Submission of papers is due by August 5th and in-person presentation at the conference is not required for publication. Conference registration and additional details are available on the web at www.tapr.org/dcc (TAPR, ARRL)

BREAK 2

Here when you need us 52 weeks a year. We are the Amateur Radio Newsline, with links to the world from our only official website at www dot a r newsline dot

o-r-g.

(5 sec pause here)

**

NAMES IN THE NEWS: HELPING HAND NET

We want to take a moment to welcome a new and very interesting net to the Amateur Radio Newsline family. It is on the AD6XK repeater here in Los Angeles California on 145.440 MHz.

What makes this net very special is that its Control Operator Simon Rosconi, K6DXN, is visually impaired. According to Dave Estrada, KD6HDX, Rosconi lost his vision at age 6. Estrada says that even without sight, Rosconi works 40 hours a week, and still finds time to volunteer his time as control operator for the nets.

But Rosconi is not the only vision impaired ham involved. Estrada tells Amateur Radio Newsline that Brian Coponiti, KG6BVO, who is also partially blind, has also volunteered. Coponiti downloads and plays back Amateur Radio Newsline to the net.

Estrada adds that this particular repeater group also has two other operators that are visually impaired. They are Gary La Duke, WB6WJW and Ivan Simer, K6TTA. (KD6HDX)

**

NAMES IN THE NEWS: EDWARD T. CLEGG, W8LOY FAMILY CELEBRATION

A few weeks ago we told you about plans by the family of the late Edward T. Clegg, W8LOY, to celebrate the life of this ham radio pioneer. The gathering is being planned by Ed’s widow Martie, her daughter Linda and Linda’s husband Rob Mc Guffie, K2HZN. Recently, RAIN producer Hap Holly, KC9RP, had a chance to speak with Rob about the upcoming event:

--
NO TEXT AVAILABLE – AUDIO ONLY
--

Hap conducted an extensive interview with Rob Mc Guffie. It really tells the whole story of Ed Clegg and his famed Clegg Labs. Part 1 is online right now at www.rainreport.com or by telephone at 847-827-7246. (RAIN)

**

RADIO REGULATIONS: AVOIDING A PHONE NUMBER CRUNCH

The nation's supply of telephone phone numbers is depleting rapidly and the government is taking steps to make sure what is left lasts longer. Amateur Radio Newsline’s Henry Feinberg, K2SSQ, has more:

--
Over the past several years, area codes have multiplied to cope with the

explosion in technology. Regions have responded by splitting up area codes among geographic areas or laying another area code over an existing one.

But in 1996 the Federal Communications Commission banned such overlays dedicated to specific kinds of technology. The Commission enacted the ban because it considered separate area codes for cellular telephones phones and pagers unfair to wireless companies and their customers. This is because everyone would have to dial 10 digits instead of seven to reach wireless customers.

But states including California, Massachusetts and Ohio had been been asking for ways to prevent existing area codes from running out of phone numbers, the agency said. The FCC says that it will now hear proposals from states on how they intend to conserve area codes on a case-by-case basis, including plans to use technology-specific area codes.

For the Amateur Radio Newsline, I'm Henry Feinberg, K2SSQ, in West Orange New Jersey.

--

The FCC, which is responsible for overseeing the supply of phone numbers, says that without action the number pool will run out in less than ten years. (FCC)

**

HAM RADIO BUSINESS: A NEW HOME FOR VERTEX STANDARD/YAESU

Vertex Standard USA, better known in ham radio circles as Yaesu, is moving to a huge, beautiful new facility. The new address is Vertex Standard U-S-A, 10900 Walker Street, Cypress, California, 90630. The new main phone number is area code 714-827-7600. All e-mail addresses will remain the same but telephone extensions will change. Vertex Standard makes the move -- no joke -- on Monday, April 1st. (Vertex-Standard)

**

INTERNATIONAL-CANADA: VE7BFK IS NEW RAC ARDF COORDINATOR

Radio Amateurs of Canada has named Gordon Young, VE7BFK as it's news R-A-C National Amateur Radio Direction Finding Coordinator. Young replaces Perry Creighton, VA7PC who held that appointment for the past several years. (RAC)

**

CONTESTS: SOUTH WEST OKLAHOMA SPRINTS

The first ever South West Oklahoma Spring Sprints sponsored by the Lawton VHF Contesting Club will take place in just a few weeks. Sprints are short period contests held primarily on a specific band or using a specific mode. The South West Oklahoma Spring Sprints are band exclusive. The 2 meter sprint is on April 1st from 7 pm to 11 p.m. Central U-S time. The 70 centimeter sprint is April 13th also from 7 to 11 Central. Both are open to all Oklahoma hams living south of Interstate highway 40 and West of Interstate 35. For more

information e-mail ne0p@arrl.net (VHF Reflector)

**

DX

In DX, K8PT and K3PLV are in the Channel Islands and operating as MJ slash K8PT and MJ slash K3PLV from Jersey through the 19th of March. The emphasis is on CW and RTTY in the WARC bands during daylight and 30, 40 and 80 meters during the evenings. Q-S-L as directed on the air. (RSGB)

Also word that Laurence Howell, GM4DMA, who is now resident in Anchorage, Alaska, will be travelling to warmer climates. This, as part of his work for the youth development charity Raleigh International. Howell say that he plans to be active as V51 slash G4DMA from Namibia from the 16th of March for two weeks. Look for him on 160 through 6 meters as his work schedule allows. (RSGB)

**
THAT FINAL ITEM: A WEDDING AT HAMVENTION 2002

And finally this week, get ready for a first. The first ever wedding to be held at the Dayton Hamvention.

No, we are not kidding. For the first time in Hamvention history, wedding vows will be exchanged at the show. This as Cyndi Krieger and Mark Elliot, N8WZW, will be married Saturday, May 18th at the HARA Arena during Hamvention 2002.

Mark and Cyndi met about thirteen years ago through a mutual friend. On their first date Mark and Cyndi went out for dinner and a movie. According to Hamvention sources, they have been an "item" ever since.

Mark introduced Cyndi to amateur radio by going to a hamfest. Cyndi had no idea what a hamfest was, but it sounded interesting. It was and she was hooked! Cyndi is now studying for her license and may test for it before Hamvention weekend.

Why get married at Hamvention? Mark and Cyndi couldn't think of a better place to share their love for each other and for amateur radio than by getting married at the world's largest amateur radio trade show. The ceremony takes place at 3 PM in Forum Room 3 immediately following the Amateur Radio Newsline produced Ham Radio Town Meeting. (Hamvention (r))

> are you so sure to be in the right part?
> Please ask about the eh antenna to those many italian hams that are
> successfully using it.

I once worked a 3000+ mile CW QSO using my dummy load as an antenna. This was on 40 meters in the novice segment.

Being able to have long QSOs is no indication that the antenna is good. It is always possible that the feedline is doing the radiating, and the "antenna" is just producing heat.

Your claims are meaningless. You need to publish such MEASURED values as field strengths at given distances from the antennas (your antenna AND the dipole), transmission line currents (if coax, then currents on the outside of the coax as well), VSWR at antenna, antenna input impedance at measurement frequencies, feedline impedance, coax and connector losses, etc.

In my third edition of Terman's _Radio Engineering_, he uses "ground wave" the same as I did in my explanation, and "space wave" in place of what I've called "sky wave". I don't find any mention of "surface wave" in the book, although some writers use this in place of "ground wave". In the source you quote, where a "ground wave" has two components, does Terman speak of any radiation other than the "ground wave"? It seems rather odd to speak of a "ground wave" having a "space wave" component.

You seem to be adding some words and interpretations all of your own, which make the whole thing seriously askew from reality.

It's very easy to add your own interpretations into something that isn't easy to understand - and yagis are not easy to understand at a first reading, or even a second or a third - so I strongly suggest that you re-read those books, and concentrate on what they really do say.

>the boom is located at the neutral point of the sign wave that travels
>out from the feed point of the dipole elements (center)

The "neutral point", as you put it, is just that - a point of zero size. The boom has a finite thickness and so it *does* have a detectable effect on the element.

It's also not accurate to think of the variation of current or voltage along the length of an element as a "travelling wave". It isn't going anywhere - the voltage and current distributions on the elements are best thought of as permanent *standing* waves. They E/I distributions have the same major features as sine/cosine waves (maxima and minima in the same places) but the shapes of those distributions differ a little from one element to the next.

Even more important, the overall amplitudes of the E/I standing waves are different on each element - often very different.

When you put a conducting boom in the middle of the element, you change its E/I distribution - not much in typical HF beams where the boom diameter is a small fraction of the element length, but even that can be enough to affect aspects of performance that are very frequency-dependent, such as front/back ratio.

On the other hand, when you're using a one-inch boom at say 1.3GHz, that is equivalent to a boom diameter of about 8 feet at 14MHz, so of course it has a very significant effect. That effect can still be allowed for, by making the elements longer, but then the correction becomes very large.

The correction depends on the element mounting method, and on the boom diameter in relation to the wavelength. Something else that you won't find in the books yet, because it's still a developing area: when boom corrections are large, the correction also becomes a function of the element lengths and diameter, so it isn't quite good enough to use a single value for all elements - see the article by VK2KU in QEX a

couple of years ago.

>The Reflector and Director(s) have the same potential electrically by
>inductance

You never read that in any book, for sure. As I said at the beginning, please do go back and read those books again, and concentrate on what they actually do say... as opposed to what *you* think they're trying to say. That difference really does matter.

How far back to the removable parts of your center hump go? I've had
fair luck with routing through the back seat, and under the center
console to the dash. It left about 6" of coax exposed, but in a
fairly safe spot.

All my rooftop runs go behind the trim panels. This not only keeps
the coax out of sight, but it also gives an opportunity for visual
inspection of existing wiring. Spotting a rather toasted wire in the
YL's car during a feedline install turned a not-worth-the-expense
repair into a five minute splice job to get the interior light
functioning again.

Out of curiosity, how the hell does one get those things off without
scratching the paint? I've thought about getting one when I upgrade,
so I can put an HF rig in the YL's car without drilling any more
holes, and be able to move it to any other car that I use for a while,
but it seems the only way to remove the four or six magnet versions
would be to pry them off with a crowbar.

Heck, I've got the MFJ 5" magmount as my backup, and without the
antenna attached, there's no easy way to get that thing detached.

For prctical purposes I would have thought the width of the boom has a
negligible effect on resonant frequency of an element. The boom merely
replaces the small portion of the element it displaces - albeit of larger
effective thickness.

The most critical dimension, the distance between the extremities of the
dipole, remains sensibly unaffected.

The effect of the boom probably has a smaller effect than the diameter or
thickness of the element itself because it extends over a much smaller
fraction of the overall element length.

Bill,

I've always followed the out of sight, out of mind rule. On all my HF installations I route the cable through the trunk, under the back seats, under the kick panels and bring it up under the dash. And don't lay the coax under any carpet where there will be feet! After a while it will get flattened and pinched. I use small cable ties to secure everything, and lock plugs on the carpet to hold everything in place. Just make sure to check for and RFI on the rig before you secure everything down. I followed the same rules installing my sound system (multiple amps in the trunk) and have not had a single problem in the 3 years I've owned the car.

Good luck,

Max

Roy Lewallen wrote:
"Energy propagated by ground wave follows the contour of the ground."

That is exactly what I would say too.

I don`t know what edition this copy of the "Radio Engineers` Handbook" is. Much of my library was ruined by a flood here in June 2001. Post flood, I could separate some pages in this volume, others I can`t. Just inside the front cover is stated: "The quality of the materials used in the manufacture of this book is governed by continuing postwar shortages". That approximately dates it.

On page 674 Terman says: "The ground wave is here considered to be that portion of the radio wave that is affected by the presence of the ground and that would account for all the energy reaching the receiver if it were not for ionospheric waves (sky waves) and tropospheric waves.

The ground wave can conveniently be divided into two components, a surface wave and a space wave. The surface wave travels along the surface of the earth. The space wave is the result of two component waves as illustrated in Fig.1, namely a direct wave and a ground-reflected wave. When transmitting and receiving antennas are both at the earth`s surface, these two components of the space wave are equal in magnitude (seems Terman assumes a perfect reflection here, but guess that it makes no difference if the result is that the space wave goes away upon contacting the ground) and opposite in phase, thereby canceling and leaving the surface wave as the only component of the ground wave. This is the case of "ground-wave" transmission of broadcast frequencies. However, as the antennas are raised the amplititude of the space wave rapidly increases, and it soon becomes the principal part of the ground wave. This is the condition existing at ultra-high frequencies when the antennas are raised a few wave lengths or more above the earth.

The magnitude of the ground wave, and of its individual components, the space and surface waves, is influenced by the resistivity and dielectric constant of the earth, the frequency, the height of transmitting and receiving antennas, the earth`s curvature, the distance to the transmitter, and the variation of refractive index of earth`s atmosphere with height.

There`s lots more, but I`m suffering eye and other strains trying to perfectly copy the print.

Best regards, Richard Harrison, KB5WZI

I have little experience with coax under automobile floor mats but lots of experience with hundreds of Motorola control head cable installations under the floor mats. We always used RG-8 cable with the radios and it will stand a lot of abuse. We tried to route the control head cables along the door thresholds where they were not subject to being stepped on. But not all installations are perfect. None the less it may be surprising that I never, ever, heard of any damage or problems due to routing a cable under a floor mat.

Best regards, Richard Harrison, KB5WZI

5439. gmrs manget mount antenna question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-21 16:34:03 UTC

Im looking for an magnet mount antenna to work with a GMRS portable
radio. Anyone know a good place to order one? I was hoping for one
with a BNC connector.
Thank-you
Dan9125@aol.com

In that case you would often be disappointed with the results. A whole generation of yagi builders found that out the hard way.

This is really not a matter for speculative debate. There is a lot of published experimental information about boom corrections, as they apply to various HF and VHF/UHF element-mounting methods, for example the QEX article by VK2KU, the ARRL books by Lawson (SK), Leeson, the ARRL Antenna Handbook, and various VHF/UHF books including 'The VHF/UHF DX Book'.

>The boom merely
>replaces the small portion of the element it displaces - albeit of larger
>effective thickness.
>
Yes and yes - but "small" is often enough to make a significant difference.

>The most critical dimension, the distance between the extremities of the
>dipole, remains sensibly unaffected.
>
That's "voltage thinking". Much more important is that the boom partially shunts the element's magnetic field at the centre where it is most intense. The shortening effect (in other words, the amount by which the element has to be lengthened to compensate) is typically a significant fraction of the boom diameter. At HF, where broad mounting plates are often used, the shortening can actually exceed the boom diameter.

>The effect of the boom probably has a smaller effect than the diameter or
>thickness of the element itself because it extends over a much smaller
>fraction of the overall element length.
>--
That is true, but as I said:

>> even that can be
>> enough to affect aspects of performance that are very
>> frequency-dependent, such as front/back ratio.
>>
It is difficult to accurately model boom effects with a program such as EZNEC, but such programs *will* show you how sensitive certain aspects of yagi performance can be to small changes in effective element length. That is your cue to go to the published references, find out what boom

corrections will apply to your element mounting system, and make sure
you use them.

Joe Jones wrote:
"Do the reflectors and directors need to be insulated from a conducting boom?"

No.. But the lengths are slightly different for parasitic elements which are not insulated. It`s because the resonant length of an element is affected by its diameter as well as the length of the element. The effective diameter of a non-insulated element is slightly affected by its boom contact.

My book specified shims should be used on undersized masts and implied that they were included. They were not.

Using a caliper and doing some math, I determined that one half of a mast section would make the proper shim to put the mast in the correct position. Although my beam has turned on the mast once in high winds, the mast has never turned in the rotator.

My Rohn is used but I am fairly certain it is #25. It is 12+ inches on a side., I tried all sorts of positions to work the rotator inside the tower, and figured the only way to get the rotator inside the tower without pulling a diagonal, was to unhook the top section and put the rotator in from the bottom. I was not about to do that as it would make future servicing a nightmare! My Rotator is the G450 A not the XL. Perhaps there is a difference in case size, although one would expect that the light duty rotator I have would be the smaller of the two.

I had heard of "space wave" in the context that Ternan uses it, but I don't use that a whole lot because it seems to confuse people. According to Termans description, the tests I ran on 10m used the "space wave". But myself, I tend to just lump them both together and call both the ground wave just for simplicity. But I still maintain that it doesn't matter for my purposes, as all I'm demonstrating is that the antenna is radiating at the "low" angle. What it does after it leaves the antenna and passes my "target station" doesn't matter for my uses. I still think using the ground or "space wave" is a good way to test lower angle performance. IE: below 10-15 degrees or so. It demonstrates that putting a vertical at 1/2 wave up or higher doesn't kill the low angle performance near as bad as you might think if you went by modeling alone. Besides, in many cases the max TOA is not too many db more than the lowest gain angles. Sometimes only 3-4 db or so. So thats not even an S units difference. Say if you had a vertical that had 6 dbi gain at 35 degrees, and 0 dbi gain at 5 degrees. Thats only an appx S unit's worth of difference to distant stations that would be receiving each of those selective waves not counting attenuation from the ionosphere ,etc. What happens after it leaves the antenna...I'm not concerned about that. MK

Stevo wrote:
"The application guide for the IC says that the impedance is approx. 2 Mohms."

If that`s an input of 2 megohms, you don`t need to try to match it. You connect your tuned circuit directly across an impedance that high. Don`t sweat the reactance. You are going to add a lot of capacitance to your ferrite loop to resonate it at 60 KHz.

You probably don`t have a grid dip meter or selective voltmeter. You need a signal generator that tunes a range which includes 60 KHz. You can check circuit resonance by radiating a signal into the tuned circuit and checking circuit output. You need an isolation amplifier with high impedance, perhaps your receiver chip, to check for resonance.

Terman says:
"The design of coils with magnetic cores is normally carried out by a cut-and-try process."

You pick a cross section and space available for a winding and try wire sizes and details. Terman has numerous tables to help. Reg may even have a free program for calculations.

You increase pick up with a longer rod, or an external antenna coupled to your coil in a way which won`t detune it too much. Your Q will be limited by re-radiation which can`t be helped when you are using the coil as an antenna. Impedance matching is impractical.

Are you talking about the volume control on receive? Or are you
talking about the amount of deviation on transmit? You can find the
information you want on the FCC website. The FCC ID is AAO1900903.
Be aware that it will take a calibrated audio generator and a
deviation meter to set the deviation correctly. You may just have a
defective unit. I would compare it against another first.

As a rough guide, by what percentage does the boom in a typical 10 meter dipole change the resonant frequency relative to a boomless dipole, the dipole end-to-end distance remaining the same in both cases ?

And does inserting a boom increase or decrease the resonant frequency, again maintaining the end-to-end distance unchanged ?

The boom "partially short-circuits" the middle of the dipole, making it
electrically shorter and thus raising the resonant frequency.

>
>As a rough guide, by what percentage does the boom in a typical 10 meter
>dipole change the resonant frequency relative to a boomless dipole, the
>dipole end-to-end distance remaining the same in both cases ?
>
For an HF dipole the main effect is likely to be due to other metalwork
(eg plates for U-bolts) rather than the boom itself, but as a *very*
rough guide there might be a 0.5-1% increase in resonant frequency. That
may not seem a lot, but it's always difficult to make an HF yagi cover
the whole band with good front/back ratio, so that small change when the
yagi is built can really mess up the careful computer design work. It
can be enough to move the frequency of best front/back ratio upwards
from the CW segment of the band to the phone segment, or a
phone-optimized yagi clear out of the band leaving very poor performance
at the low end.

At VHF/UHF the boom diameter is generally a much larger fraction of the
element length so the shifts can be 5% or even more, which is enough to
ruin the yagi's performance completely.

Reg wrote:
"As a rough percentage---?"

I don`t have a clue.

The fatter a wire is, the less self inductance it has for a given length.

The self-inductance of an antenna conductor is part of the total self-inductance of an antenna circuit. It is also a part of the mutual inductance of an antenna circuit.

I don`t know the percentage change in parasitic element length that occurs when connecting the element to the boom.

I haven`t compared lengths of elements insulated vs elements connected, though I`ve built both types of yagis amd both types worked as advertised.

From glancing at TV antennas around me, I`m sure there is little cost benefit in using insulators for parasitic elements. The consumer TV antennas around me don`t insulate the parasitic elements.

My guess is that a connected boom makes the conductor (element) fatter for a short distance, thus the inductance may be smaller for a short distance. That might require a slightly longer conductor.

On the other hand, there are antennas of a different type that are shorter when fatter, for the same frequency.

I wouldn`t be surprised if some reader knows all about how the lengths change with and without insulation of the parasitic element connection to a yagi boon. It isn`t me.

Best regards, Richard Harrison, KB5WZI

Thanks Cecil for confirming what I thought you did.

So there's something wrong either with conclusions deduced from your experiments, or with the uncertainty of data inserted in Eznec. Take your pick! ;o)

But I know you don't take me too seriously. Most of us, both amateurs and professionals, are inclined to suffer from delusions of accuracy regarding both computer programs and our own observations. It's all due to neglect of elementary stastistics in our school days and present-day schools. Much of the rest of the world is better educated. We should heed them.

Cheers, Californian dry red tonight, Reg, G4FGQ.

Sorry Ian,

Trying to over simplify things in my reply to the original post. The question was to do with how come some designs are insulated while others are not. Just a simple depiction showing it could be either way.

I sure can't blame the guy for being confused... I wondered the same thing for the longest time. I can sit down to read the ARRL antenna book and it takes 2 days to figure out a simple answer to a question some times. Like some of the threads I've followed on this NG hi hi!

Don't get me wrong, I love following this NG. But sometimes a simple question can spark a debate that rage's for days or weeks, back and forth (not to mention off into theoretical science and beyond) leaving some of the audience and/ or poster wondering what the final answer was. Maybe even what the question was in the first place by the time the dust clears.

Better entertainment then the TV!! :-)

take care.

==========

Tony, your modest apology does not really fit the bill. Don't stand for any intimidation. ;o) Most other contributors are guilty of overcomplicating what is a relatively trivial matter. If they should think about it.

The presence of the usual yagi boom is of much less consequence than the combined effects of the diameter of the antenna element, the height of the antenna above ground, the presence of trees, buildings, mast, power lines, phone lines, TV antennas, etc., in the near vicinity, and certainly a smaller effect than the disposition of and the ever present radiation from the feedline. KTIP = Keep things in proportion.

Yours, Reg G4FGQ

The calculation is pretty trivial. Say that the rotator manual states that
the proper diameter mast is 2.5 inches. Now also assume that the diameter
of mast that will fit through the top of the tower is 2.0 inches.

The difference is 0.5 inches and the shim thickness must be 1/2 of that
difference or 0.25 inches. The shim goes between the rotator body and
the mast - not between the rotator u-bolt clamp and the mast.

Jess,

What I would do is simply wind a small coil about 1 1/2" dia of about 11
turns and 14 ga.
copper (doesn't have to be copper) solid wire. Attach one end to the bottom
of the an-
tenna on the stud (+) and the other end to ground nearby (-). Trim if needed
and you might
be surprised at how well it will work.

That is too close for comfort and might be the reason for your unhappiness with comparison of both antennas. There is some coupling going on.
If you want to compare two antennas, they should be at least one wavelength apart.

It looks like nothing more than a twin lead J-pole inside
a PVC pipe. See:
http://www.qsl.net/ke3fl/gif/jpole-tv.gif

5465. Q: multi-band vertical wire end-fed antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-22 04:01:50 UTC
From: Dust Might <alfaromeodiscovolante@hotmail.com>
Message-ID: <O0ym8.3000$oi.148952@newsread2.prod.itd.earthlink.net>
Source record: 146352

I currently build and use the J-pole wire half-wave design vertical mono-band end-fed antennas for 20, 17, 15, 12 and
10-meters, hung from a small rope 'n pulley 60-feet up a tree in my back yard (only one antenna at a time).

I have recently swapped for an HF plus 6-meter rig and obviously can build this (described above) antenna for 6-meters,
but since I have so much height to play with, what about an end-fed wire half-wave antenna combining 6 & 2 meters? OR
how about a 6 meter end-fed vertical wire antenna with higher gain (more than half wave)?

The J-pole design I'm building is constructed out of a half-wave of 14-gauge electrical wire over a 1/4 wave of Ladder
Line with rg-58 coax soldered across each side of the Ladder Line near the bottom of the J.

Any suggestions without me having to go borrow someone's ARRL Antenna guide book?
Thanks,
-Dusty wd4dx

5466. The transformer in a noise bridge circuit

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-22 05:24:40 UTC
From: jason_hsu@my-deja.com
Message-ID: <f7d9a152.0203212124.21d541f9@posting.google.com>
Source record: 146353
Cross-posted to: rec.radio.amateur.homebrew,rec.radio.amateur.antenna

As I mentioned before, I would like to build a modified version of the SWR noise bridge shown on page 27-25 of _The ARRL Antenna Book_. The schematic is available at http://www.qsl.net/wq1rp/noisebrg.htm, as the New England QRP group sells a kit.

I should note that my version of the noise bridge will be an improved version of the MFJ-212 Matchmaker (http://www.mfjenterprises.com/products.php?prodid=MFJ-212). Please note that the MFJ-212 does NOT have the resistance or reactance dial, and my noise bridge will not either.

The NE555P chip interacts with the diodes and resistor to produce an output voltage that consists of a 1000 Hz square wave. When it interacts with the Zener diode, a broadband RF noise source is produced. The 2N2222A BJTs amplify the RF white noise signal.

Exactly what does the transformer and the rest of the circuit do? My general understanding is that the transformer sends the RF noise into the transmission line. Since there turns ratio is 1:1, the voltage and current ratios are 1:1. The RF noise is sent towards the antenna through the coaxial cable. Any mismatch between the coax and antenna results in reflected RF voltage, which propagates towards the receiver. The larger the reflected RF noise signal, the louder the noise you hear. Adjusting the resistance and reactance dials for the minimum noise reveals the feedpoint impedance.

Some questions:
1. What do the 82 microfarad and 47 microfarad capacitors between the transformer and antenna do? Are they part of an SWR bridge circuit?
2. When the RF voltage returns to the noise bridge, what prevents the transformer from coupling the RF back to where it originated? Or is it stopped at the back end of the last amplifier? (Sorry, I haven't studied transformers in 8 years and never really understood them in the first place.)
3. How would I modify the noise bridge to (gasp!) omit the resistance and reactance dials? Some of you might say that this circuit would no longer be a noise bridge, but the MFJ-212 lacks those dials. I simply want to send the RF noise to the receiver so that I can adjust the antenna and tuner for minimum noise (a byproduct of minimum SWR).
4. Where can I buy an Amidon BLN-43-2402 ferrite binocular core? What acceptable substitutes are there?

I have the same coil and have not experienced this
problem (mine is UV deterioration of the Delrin
rod -- cured with a paint job). It would seem
to me that a dab (just a dab) of epoxy in those
grooves, a little bit of clamp pressure to hold
the wire in the groove and an overnight cure would
fix it.

Reg joined this discussion yesterday, with a question that implied he
had never even heard of boom corrections. Today he's giving out advice.

In 35 years of building, designing, modeling and above all *using*
yagis, I've seen all the mistakes and made most of them myself -
including the one Reg is making about boom corrections.

Reg will always go his own way, but I'd hate for any 'innocent
bystanders' to follow his advice about this. If you ignore the boom
correction, you will cut all the elements too short, and your yagi will
perform worse than it should - at VHF and above, a lot worse!

5483. Re: The transformer in a noise bridge circuit

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-22 17:30:24 UTC
From: richardharrison@webtv.net
Message-ID: <9367-3C9B6A30-53@storefull-2391.public.lawson.webtv.net>
Source record: 146271

Jason Hsu wrote:
"Exactly what does the transformer and the rest of the circuit do?'

The transformer is half the bridge circuit. The transformer has a center-tapped secondary. When identical ciurrents are supplied from ends of the secondary, identical and opposite currents flow from a center-tapped load to the centertapped secondary, if there is any current at all.

Another way to look at this is as a center-tapped voltage source connected to a center-tapped load. As there is no voltage difference between the center taps, no current flows between them.

Bridges are usually just two voltage dividers. When balanced, the ratios are equal, and there is no voltage difference between the two voltage divisions.

A tapped transformer can replace one of the dividers and the bridge excitation source too.

Jason also wrote: "Since the turns ratio is 1:1, the voltage and current ratios are 1:1."

True, when the bridge is balanced.

The transformer could be 2:1 or some other ratio as long as the load had the same ratio of impedances for a balance.

Jason also wrote: "The RF noise is sent towards the antenna through the coaxial cable."

The bridge need not be complicated by traveling wave considerations to explain its function. The noise bridge functions as an a-c bridge. The noise bridge is identical to a capacitance bridge except for the component values and the single frequency source usually employed in the capacitance bridge.

Jason also wrote: " What do the 82 picofarad and 47 picofarad capacitors---do?"

The book tells you, they weigh the range between capacitance or inductance.

If the unknown were a pure resistor, its value could be determined using only a purely resistive balance control.

If the unknown is an inductance, a capacitive reactance larger than the inductive reactance (a small capacitance) can be placed in series with

the unknown inductance. All the inductance is canceled and there is capacitive reactance to spare and be measured as the unknown reactance. By determining this reactance, we can infer the value of the inductance.

Jason also wrote: "When the RF voltage returns to the noise bridge, what prevents the transformer from coupling the RF back to where it originated?"

Draw a transfortmer with a primary and a center-tapped secondary. Load each end of the secondary with identical resistors to a common point.

Place a telephone receiver between the center tap and the common point.

Place a telephone transmitter across the transformer priamary.

Voila! We have a hybrid! One resistor is a 2-wire telephonne line (believe me!). The other is a balance network (identical in impedance with the phone line).

When the transmitter talks, the receiver is silent (We`ve eliminated the "side-tone"). Half the transmitter`s output has been absorbed by the balancing resistor. The other half has been absorbed by the 2-wire telephone line.

Now back to Jason`s question. This hybrid is the same as the noise bridge circuit. The 2-wire line is in the same place as his antenna feedline. The telephone transmitter is in the same place as his noise generator. The receiver is in the same place as his bridge detector.

So when energy comes back from the line, be it telephone or antenna line, some is lost in the balancing network, and some is coupled into the primary. This causes no problem to the telephone transmitter and supplies sound to the telephone receiver as it is intended to do.

The same will happen in the noise bridge as the circuit is the same. Reflected energy from the antenna feedline will reach the noise generator, but it certainly is smaller than that being generated by the bridge generator and causes no damage. The reflected energy will also feed the bridge detector, and correctly indicate a mismatched load..

Jason also wrote: How to omit the dials?

Replace the balancing network with 50 ohms. You will get balance by adjusting the load.

Jason also wrote: "Where can I buy an Amidon---?"

Surf the net.

This is the point of my suggesting YOU determine the minimum circuit configuration of a bridge. Jason, you should start doing your own homework by now and explaining to US how it works to both confirm your understanding and become an active rather than passive participant.

>
>Some questions:
>1. What do the 82 microfarad and 47 microfarad capacitors between the
>transformer and antenna do? Are they part of an SWR bridge circuit?

There are only six (6) capacitors shown, none more than 0.01 ï¿½Fd. You need to answer more questions than ask them at this point.

>2. When the RF voltage returns to the noise bridge, what prevents the
>transformer from coupling the RF back to where it originated?

Nothing - the consequences doesn't matter either. It is enough to accept that it does couple back (the whole point of an imbalance).

>Or is it
>stopped at the back end of the last amplifier? (Sorry, I haven't
>studied transformers in 8 years and never really understood them in
>the first place.)

Understanding the minutia of transformers is wholly unnecessary, they can be treated as black boxes if first you accept their principle application of isolation and balance. Do you grasp the operational necessities of the simple DC Wheatstone Bridge? No transformers there to cloud the issue, and everything works the same as the noise bridge. Visit the engineering section in a library at a community college for an hour.

>3. How would I modify the noise bridge to (gasp!) omit the resistance
>and reactance dials? Some of you might say that this circuit would no
>longer be a noise bridge, but the MFJ-212 lacks those dials.

The facetious reply would be to peel off the labels and remove the knobs.

Omitting the components would render it useless - unless you just want to listen to noise for no purpose.

>I simply
>want to send the RF noise to the receiver so that I can adjust the
>antenna and tuner for minimum noise (a byproduct of minimum SWR).

That won't happen in the direction you are moving.

>
>Jason Hsu, AG4DG

Hi Jason,

I would have offered:
http://www.bytemark.com
as a source, but they seem intent on commercial suicide over the net by taking down working pages to replace them with the announcement of a new site being built. As alta vista revealed 515 references to the query "amidon ferrite" you could as easily find another vendor one would think.

I don't know why you are looking into binocular cores, but that is a move in the right direction; however, do you have a good reason (the right one that is)? Given your professed ignorance of transformers, you are in over your head to make changes in circuit design in advance of actually building a working, original model.

>Chris
>WB5ITT
>Broadcast/telecom engineer
>ARRL Technical Specialist

Yes, but very few if any of the 5/8 GP designs for 2m are properly designed. In your broadcast case, you have the needed ground radials to provide a decent pattern. Most elevated 5/8's for 2m use only a set of 1/4 wave radials. This provides for a lousy pattern from a 5/8 GP. The pattern is skewed upwards off the horizon. You do not get this skewing on a 1/4 wave GP assuming the feedline is not radiating. So in the real world, many times the 1/4 wave will do better at the low angles needed for local 2m work. This is not just random theory. I have tested this in the real world. I once made a high quality 2m 5/8 GP from a larson coil. I used 4 1/4 wave radials. This antenna was greatly inferior to my 1/4 wave GP at the same height. I took it down after one day. Now, on the HF bands, there are many cases where the 5/8 will be the better antenna of the two, but on HF, the ultra low angle performance is not near as critical. I tested all lengths of verticals on 10m, and on that band the 5/8 was the best. But I also used longer radials on 10m, not 1/4 wave. To properly design a 5/8 antenna for 2m, I think the best route is a dual 5/8 antenna. IE: collinear. Anyway, running a ground mount 5/8 on the AM-BC band, and one on 2m elevated, are two totally different worlds. Anyway, I totally stand by my statements. I've tested them in the real world. I'll never use a "standard" 5/8 GP with 1/4 wave radials on 2m again. It was the pits. If I were to build a 5/8 antenna for 2m it would look like this: http://web.wt.net/~nm5k/58dual1.htm
The other pages show patterns from "standard" 5/8's antennas. Compare the standard 5/8 with 1/4 wave radials on page 3 to my improved version on page 5. No contest...
BTW, your call looks familiar.. Houston maybe? MK

The transformer is an integral part of the bridge. To get zero going
to the receiver, the voltage at the top end and at the bottom end of
the transformer must be 180 degrees out of phase and equal magnitude.
That happens if the net impedance load on each end of the transformer
to common is the same. -- I'm not sure what schematic you're looking
at...I have the noisebrg.htm schematic up, and it shows only a 27pF
cap feeding the antenna from the transformer. If the "unknown" is
then 50 ohms, you get balance with a 27pF capacitance on the variable
and a 50 ohm setting of the variable. If you want to omit the
variables, just use a 50 ohm fixed on the top end and replace the
variable cap with a short circuit; on the bottom end you could omit
the cap (replace with a short) or use, say, a tiny 0.01uF cap to block
DC (dunno why you'd need it, though).

You should be able to get an Amidon part from Amidon Associates,
though when I visited their web site recently it looked like they are
discouraging direct purchase of small quantities. Do a Google search
for Amidon and you'll turn up other sources.

Cheers,
Tom

I will second that.
One measurement is better than 1000s of theories :-)
Same experience here. Friend, ex VE3NE SK who worked for Collins did some tests
5/8 vs 1/4 wave verticals on VHF and the clear winner was 1/4.
That's what they used for all the mobiles.
This can be easily verified, just tune in fringe 2m signal and swap antennas
and you will be convinced.

IronHead wrote:

> My next antenna is going to be an end fed zepp for 40M.

Hi, "Ironhead,"

As Cecil says, a balanced dipole can be used
for several bands. J-pole/end-fed Zepp antennas
are intended as single band antennas
which could be just what you need/want.
See Cecil's web site http://www.qsl.net/w5dxp
for ways to match a dipole/feedline system
for many HF bands.

According to George (V3ERP, HAMCALC) Murphy's
version of my version of Gary (N3GO) O'Neil's
end-fed-zepp/J-pole program, starting dimensions
for a 40m Zepp are:

freq. = 7.1 MHz
end-fed 1/2 wave radiator = 65.8 ft
(Cecil's 66ft looks good.)
[3000 ohm radiator impedance assumed]

[300 ohm twinlead matching sections (not 450 ohm),
velocity factor about 0.80]
series matching section = 26.3 ft (85.34 e. deg)
[50 ohm feed point]
shorted shunt matching stub = 3.58 ft (11.63 e. deg)
[Total matching about 29.9 ft for 0.80 v.f.]

[Start a little long and trim the stub.]

Total length = 95.7 ft if stretched out/up straight.

[Note: total twinlead about 96 elec. degrees,
not the traditional 90 deg or 1/4 wavelength.
Smith Chart and t-line calculations agree.]

Some recommend making a choke coil of the coax
feed at the antenna for a balun function.

See Steve Yates's (AA5TB) web site
http://www.qsl.net/aa5tb
for a lot more info on end-fed antennas
and a link to Gary's Communications Quarterly
article, "From J to Zepp."

I can email Murph's j-pole Basic program
(in Hamcalc for a couple of years)
and also gwbasic.exe if you don't have it.
Murph will send the whole Hamcalc package CD
(300 programs) for US$7 to cover S&H from Canada.

Let us know how you do.

Cheers, 73,

Ron McConnell

5497. Loop antenna Rectangle

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-22 23:03:47 UTC
From: "CH. TORRE" <christophe.torre@wanadoo.fr>
Message-ID: <a7gdbucjo1@wanadoo.fr>
Source record: 146285

Hello,
Search(research) shemas to make an antenna Loop rectangle. That it is sound
the impedance: 50ohms , 75 or 100 ohms for the connecting of the feeder for
a frequence of 1,5Mhz.. Is it Necessary to use a balum or can one link the
direct emeteur with the antenna with a coax of 50 ohms? Unless any depends
of the height of the antenna with regard to the ground? In +
Thank

Cris,
When using coaxial feed line it is necessary to match
impedances in some way. It can be by balun, or a 'matching'
section of feed line. A matching section of feed line is
always of some impedance value ~other~ than the impedance
of the remainder of the feed line. The most common matching
section is made using 75 ohm coax.
The antenna's height above ground does make a difference
in the antenna's input impedance.

I hope this translates well...

Source record: 146288

The wonderful patterns you see for a 5/8 wave vertical assume a perfect ground plane, flat and infinitely large. If you make an accurate model of the antenna and its mounting (e.g. including radials or a car top and body), you'll find that the expected low-angle gain often isn't there. It's not so much a problem of bad theory as it is using the wrong theory for the problem.

I guess I just do not understand the assertions that 1/4 wave works
better than a properly designed 5/8 vertical.

I have A/B tested both many times on a mag mount on the top of my car or
on my pickup truck. In marginal locations for the 1/4 wave, in no case
has the 1/4 been better than the 5/8 in accessing the repeater.

My test conditions are for distant repeaters and not in an urban
environment where more high angle signal strength might be useful.

By the way a properly designed 5/8 is not just a longer wire tied to the
coax feed line. You can get away that with the 1/4 wave however.

Aloha,
John KH7T

Yes, there are several variations of vertical hf antennas, multi or mono band, some with very short radials (do a
google.com search under *amateur vertical antenna*).

Do you have a tall tree or trees? For a real unnoticed model, I use simple home-brew end-fed wire 1/2-wl antennas on 20
to 2 meters, (a wire variation of the common Jpole design) hanging from a string, shot over a branch high up in one of
my trees. I can explain in detail if you are interested in this route.

5504. Frankenstein's transmission line

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-23 05:08:22 UTC
From: Al Lorona <w6wqc@dslextreme.com>
Message-ID: <a7h2up$l40c4$1@ID-49117.news.dfncis.de>
Source record: 146292

In the classic 1931 film 'Frankenstein' one of the more spectacular devices in the laboratory consisted of two vertical metal rods in a V configuration. An arc is established at the apex and travels upwards toward the higher impedance (wider gap) open end where it extinguishes. Immediately thereafter a new arc is struck at the apex and the process repeats.

The device approximates, at least visually, an open wire trapered unterminated transmission line.

The questions are these:

1. Why does the arc travel upwards towards the higher impedance gap?
2. What determines the velocity of the arc's ascent?
3. If the device is rotated 90 degrees so that the rods are horizontal, or upside down for that matter, does the arc still travel toward the open end?
4. If the vertical rods are parallel does the arc still travel upwards? If not why not?
5. In a tapered unterminated transmission line onto which a sinusoidal EM wave in launched and arc-over occurs will the arc travel toward the open end? If not why not?

I have not been able to find any references to this phenomena. 73, AL

This device is commonly called a "Jacobs Ladder". I built one in my high school electronics class using a 15KV neon sign transformer and some 1/8" welding rod.

> 1. Why does the arc travel upwards towards the higher impedance gap?

The arc ionizes the air and is hot. Heat causes the arc to rise.

> 2. What determines the velocity of the arc's ascent?

Not sure how to explain it, but in a room with a breeze, the speed of the rising arc varied quite a bit on mine.

> 3. If the device is rotated 90 degrees so that the rods are horizontal, or
> upside down for that matter, does the arc still travel toward the
> open end?

The arc will try to rise with the heat untill the gap between the wires is too far for the voltage to jump across. When the gap is too far for the voltage to jump, the arc dissapates and the arc reforms at the shortest gap.

> 4. If the vertical rods are parallel does the arc still travel upwards? If
> not why not?

Yes, the arc will go up. Heat again. I've seen some Jacob's Ladders where the arc would stop at the top.

> 5. In a tapered unterminated transmission line onto which a sinusoidal EM
> wave in launched and arc-over occurs will the arc travel toward
> the open end? If not why not?

Not sure on this one, but I assume it would behave the same as I describe above.

> I have not been able to find any references to this phenomena.

Go to www.google.com and do a search on "Jacobs Ladder". This page also has some construction instructions and a little discussion on theory.
http://misty.com/people/don/jacobs.htm

Hope that helps.

But you are talking a mobile antenna. I'm talking about an elevated 5/8 wave ground plane. Again two different worlds depending on the size and place of mounting on the car. I've seen a 5/8 win many times over a 1/4 wave on a car or truck, but those have much more metal area than a set of 1/4 wave radials. Also it depends on the terrain. Many in mountain or uneven alt terrains prefer 1/4 waves because they have a wider beamwidth and are less critical. But say here in the Houston area where it's pretty flat, a 5/8 is the best way to go on a car. You will have less picket fencing for one thing with the 5/8 around this area and better range usually. But a 5/8 up in the air on top of a set of 1/4 wave radials? The pits. In fact, I tried a ringo ranger 2 also around the same time I did those comparisons. "About 1984-85". The lowly 1/4 wave ground plane with 8 sloping radials was very close in performance to the ringo ranger 2 with the decoupling kit. Thats fairly impressive for an antenna that costs nearly nothing. Sure, the RR2 is tall and has a bit of gain, but if the 1/4 GP's tip is the same height as the tip of the RR2, not much difference really between the two. MK

I believe most new autos will have an existing
hole somewhere in the floor with a plastic plug in it. Run your wires thru a
hole in the plug and
put in a new plug if you remove the wires.

Tom answered your questions but apparently missed the horizontal condition
for this one. For two horizontal wires, the arc will find the point where
the wire is closest and will stay there.

Source record: 146299

Tom Kindel answered the Jacob`s ladder questions very well. It`s heat that makes the sustained arc rise until the gap is too wide. It stops and a new arc starts across the narrow spacing.

Cecil answered the horizontal tapered line question. There is no rising heated plasma propelling the arc along a horizontal line, so it stays where the cap is narrow.

In arc gaps provided across transmission lines, transformers, and broadcast radio tower base insulators for arc initiation to protect other equipment from high voltage surges, the gaps are topped with Jacob`s ladders. These would extinguish arcs from the available apparatus power which follow on after the initial surge is gone.

Problem is, the initial flashover often occurs elsewhere across a wider spacing instead of the narrow arc gap provided for the purpose. The stationary arc must be instantaneously interrupted by killing the power to the arc.

Broadcast stations often isolate the transmission line for d-c (capacitors in series with it). A d-c relay coil and its power supply are connected in series and shunted across the transmission line (r-f chokes provide isolation). Arcs in the transmission line complete the d-c circuit to the relay coil. It actuates and its contacts break the circuit in the transmitter`s interlock system, momentarily dropping the radio from the air. The relay is de-energized, the interlock circuit is once again complete, and the transmitter automatically returns to the air.

Best regards, Richard Harrison, KB5WZI

Many autos have rear mounted power raised and lowered antennas. The wire and cable for these is kept inside the car for protection.

Commercial 2-way radios are installed the same way. It`s best by test to install that way.

Yuri, K3BU wrote:
"That`s what they (Collins) used for all mobiles (1/4-wave)."

It`s been best for me too.

Broadcast radio stations do very well with 5/8-wave verticals to increase radiation in the horizontal plane. But, they don`t bang into tree limbs, bridges, parking facility obstacles, etc. The broadcaster also has 120 lengthy radials under his 5/8-wave vertical to complete the antenna`s circuit.

Mobile users have the obstacles, matching losses (A full-length 5/8-wave isn`t resonant.), and an iffy ground. So, their success is spotty.

Best regards, Richard Harrison, KB5WZI

I'd like to thank you one and all for your kind considerations of the AM radio problem I posted a couple of weeks ago. After all considerations were in and evaluated, the winner was an NE605 using the RSSI port for detection, a conventional 21.4 MHz. IF, and a toggled, or shared tone comparator. If you go through all the birdie and tweet combinations of dual IF strips working in close proximity, it is far easier to tame the beast using a single channel. Again, thanks for sharing your thoughts.

Now let me pose you one more problem and I'll be quiet for a while. Suppose you are inside a steel building (or more properly, an aluminum can) and can only have something the size of a tupperware sandwich box on the outside of the can. Anybody got any trickery to get the relative bearing on a signal in the AM broadcast band? That is, if the can can rotate (and Yan can cook) horizontally relative to the signal, how can I tell (without mechanically rotating the sandwich box, which is firmly bolted to the outside of the can) where the signal is coming from relative to one end of the can or the other? (The classic ADF question.)

I know it can be done with orthogonal horizontal loops and a vertical sense antenna and driving the loop to the cardioid null with a goniometer, but is there a better modern way to do it? I've seen switched antenna designs using pin diodes, but this was all at VHF where the antennas were comparable to a quarter wave. I need to keep the antennas inside the sandwich box.

Jim

5517. What is this antenna I just bought?

Source record: 146305

Just got back from Pickett's Lock radio rally and beside the usual
connectors and
adaptors, I bought (for £9) an active antenna made by California Amplifier -
Part No 540001.

Done various searches but come up with nowt. The seller said "It's 78MHz to 2.8GHz and requires 1.8 volts - most scanners have this on their antenna sockets."

I don't think so...................

Moving swiftly on, the entire device is encapsulated in a plastic tube arrangement, is about 24 cm long and 3 cm in diameter. Termination is a tiny SMB connector.

They had broken one open for punters to look at its innards. The antenna element appeared to be a band of 1cm wide copper wound around a expanded polystyrene former, barbershop pole-fashion. The former is about 2cm in diameter and 15cm long. This fed the amp - all the usual SMD stuff - in a tin enclosure.

Any ideas what this may be good for. Is it a helix antenna, designed for use end-onat, say 3GHz, or, as the man said, a wideband VHF/UHF omni? Any ideas?

Emailed CalAmp but they probably have better things to do.

Any thoughts appreciated - Martin

Chris Torre wrote:
"---to make an antenna loop---, for a frequency of 1.5 MHz.

You have NO sky wave at 1.5 MHz, daytimes. You must rely on ground wave propagation. There is NO ground wave propagation of horizontally polarized waves over the ocean or reasonably good earth. The only use for horizontally polarized waves at 1.5 MHz is at night at distances beyond a large skip-zone distance which omits local coverage. The only exception for local coverage using horizontal polarization is by elevating antennas to great heights so that you have a "line-of-sight" between antennas.

Horizontal loops are horizontally polarized. Their electrostatic lines of force are between different sides of the antenna and with the earth. Unless they are high above the earth, the vertical polarization this height produces is small just like their height, and doesn`t amount to much. Even with height above ground, displacement current shrinks with height, and the vertically polarized radiation shrinks too.

A vertical loop above earth can be vertically polarized. It depends on where it is fed. The problem is that it is more expensive and difficult to make omni-directional than is a single tower over a radial system. Broadcast stations the world over use vertical towers as radiators because they are best by test.

Forget a loop. It is no good for you.

Best regards, Richard Harrison, KB5WZI

>
>Jim
>

Hi Jim,

I would offer that the success of the VHF model you are familiar with
is not in the antennas being comparable to a quarterwave, it was with
the distance between them being of significant distance from the
others so that a phase difference could be easily resolved between
distant pairs.

Your descent into the AM band, as well as shrinking the distance
between sensors (antennas if you will) compounds the difficulty in
resolving phase differences (really a time difference, which resolves
to phase the be-all and end-all of finding the direction). This is
not to say it is impossible, merely expensive. Given the double
whammy, you will be looking for differences of a partial degree

(rather than 10's or 100's of degrees). This is freely translated back into time differences which are the same the world over, however you could only reliably find that difference at the zero crossing of the signal at the different sensors (antennas). The VHF model, however, can operate quite usefully with comparisons anywhere along the slope of the received signal because the physical system imposes a large phase shift between antennas in relation to the wavelength.

Your VHF model actually would have the boon of the integration of the entire wave to eliminate the effects of noise. $$On the other hand, the zero crossing mandate for the AM band also comes with the risk of noise providing false information.$$

Jess,
The 20 meter match should be with just a little more coil than the 15 meter band, Only a few turns of coil. Try cleaning the outside face of the coil with fine sand paper or emery cloth. It is touchy! a couple turns make a big difference on frequency!
Les, AA4F

You mean J-pole? A jacob's Ladder is a vertical Wire Vee that is used
to demonstrate how an electrical arc will generate heated ionized air--
the arc will slowly rise up the wires until the spread is far enough that
the
arc estinquishes and the process starts over again. You'll need an old
model spark coil or something similar to generate the HV.

Pete

Amateur Radio Newsline™ Report 1284 - March 22 2002

Amateur Radio Newsline report number 1284 with a release date of
Friday, March 22nd, 2002 to follow in 5-4-3-2-1.

The following is a Q-S-T. Ham radio and the FCC join forced to find a wayward transmitter jamming a fire department radio. This story is first on Amateur Radio Newsline report number 1284 coming your way right now.

(Billboard Cart Here)

**

RESCUE RADIO: HAMS ASSIST IN TRACKING DOWN WAYWARD TRANSMITTER

Ham radio operators teamed up with the FCC to track down a wayward transmitter. One that was making communications very difficult for the Fallbrook California fire department. It took place the weekend of March 10th. Amateur Radio Newsline’s Norm Seeley, KI7UP, has the rest of the story:

--

Milt Davies, KD6UBA, is Division Chief of the North County Fire Protection District. He was the first to identify the problem as radio frequency interference.

Davis described the annoying signal as being an unmodulated carrier pock-marked with strange data-like bursts. Sometimes the jamming transmitter was on-the-air all the time. Sometimes it was on and off. And at still other times the signal almost disappeared - transmitting only a few seconds in a 10 or 20 minute span.

Davies recognized the problem as on-channel jamming. He also knew that he needed outside help. That's when the FCC and the local ham radio community were notified.

First to try was the FCC. As you know, the agency has a series of permanent direction finding stations on the West Coast. These can be operated by remote control from Washington, D.C..

The FCC's weekend duty officer attempted to pinpoint the source of the interference using them, but with only partial success. Some of the locations were down for servicing. The result was a single line-of-bearing. This meant that the interfering transmitter could be anywhere along a 45 mile path.

To help home-in on the transmitter's location, members of the Palomar Amateur Radio Club were called out. They were asked to listen to the fire dispatch frequency and give signal strength reports on the unmodulated carrier. These

reports, coupled with the FCC's own line-of-bearing, pointed to the City of Vista, or vicinity.

Now the hunt again became the domain of the FCC. Bill Zears, the District Director in charge of the FCC's San Diego Field Office, arrived with a sophisticated direction finding vehicle. Zears drove to Fallbrook for his first good bearing. That sent him off toward the rugged eastern portion of Vista.

At about the same time, a fire broke out in the Camp Pendleton military complex which borders Fallbrook. The jamming signal was preventing firefighters working the Pendleton fire from communicating directly with their Dispatch Center.

Zears stayed on the job as Sunday afternoon turned into evening. Finally, enough direction finding bearings were available to pinpoint the wayward transmitter to a 30' tower atop a hill in east Vista.

The Vista Fire Department was called. The Battalion Chief on duty offered immediate help. It turns out that a local ham had brought him up-to-speed on the interference case earlier in the day.

Then another ham recalled that the City of Vista once had a transmitter up on the suspect peak. That old VHF transmitter dated back to the days before most communications had moved to the 800 MHz band. He also knew that the old box just happened to be tuned to Fallbrook's current VHF dispatch frequency - because that was Vista Fire's old frequency!

The crew lost no time in getting up the hill and confirming the location of the offending transmitter. Nobody knows why power was still connected. Probably an oversight by some long forgotten radio installer. None the less, it caused the Vista's Fire Department to unintentionally jam Fallbrook, but pulling the power plug made the interference go away.

For the Amateur Radio Newsline, I’m Norm Seeley, KI7UP.

--

Thanks to the cooperation of everyone involved and the tenacity of FCC District Director Bill Zears, the situation had a happy ending. (W6VR)

**

OLYMPICS FOLLOW-UP: HANDI-HAM CARRIES OLYMPIC FLAME

The 2002 Winter Olympics may be over, but now comes word that a visually impaired ham radio operator was among those who had the honor of carrying the Olympic Torch.

Kitty Hevener, WB8TDA, and her trusty guide dog SunStar, carried the Olympic Flame on Saturday January 19th. This, as it made its way to Salt Lake City Uath. Kitty’s segment took the flame up to the gates of Fort Point, in the shadow of San Francisco California’s Golden Gate Bridge.

According to the Handi Hams, Kitty Hevener, WB8TDA, is active with that group as well. Handi Hams says that she is a regular volunteer at the annual California Radio Camp held at Camp Joan Mier in Malibu California every March.

You can see photos of WB8TDA carrying the Olympic Torch at www.graystuff.com/gallery/kitty. (HandiHams)

**

ECONOMICS: JAPANS ECONOMIC RECESSION MAY AFFECT RADIO PRICES

The price of ham radio gear and other goods manufactured in Japan may soon change, but its unclear if it will be up or down. This on word that Japan's economy has fallen into the worst recession in at least two decades. The last time the Japanese economy contracted for three quarters straight was in 1993, when it shrank at around 0.1 percent each quarter. Before that, Japan had never seen even two back-to-back quarters of contraction - the usual definition of a recession - since the government began keeping such records in 1980. (ARNewsline(tm) from published news reports and ARNewsline(tm)interviews.)

**

EMERGING TECHNOLOGY: WSJT TAKING ON THE WORLD

Meantime, a new mode of operation seems to be taking Amateur Radio by storm. We have reported on it before: WSJT. And it lets everyone get in on what used to be the esoteric operation called meteor scatter. Q-News Graham Kemp, VK4BB, looks at the way WSJT is taking on the world:

--

WSJT is a digital mode, designed specifically for meteor scatter communications. It stands for Weak Signal communications by Joe Taylor K1JT. Its advantage for is that it sends extremely fast in a standard SSB bandwidth at 147 characters per second or about 1700 words per minute. By virtue of this speed it is possible to send two call signs and a signal report in a tenth of a second meteor ping.

The equipment to make WSJT contacts is fairly modest. A two meter SSB transceiver and a computer -- a Pentium, at least 75 MHz is the main hardware required. Then you need a simple PSK-31 interface box, as described in March 2000 AR magazine and some WSJT software.

An RF power output of 50 is the practical minimum, with 100 watts providing a worthwhile improvement. A major advantage with WSJT is the small antenna system required. A five element Yagi will do as well as a 10 element Yagi.

From Q-News Australia, I'm Graham Kemp, VK4BB for the Amateur Radio Newsline.

--

More information and the necessary software is at the official WSJT website. Its in cyberspace at pulsar.princeton.edu/~joe/K1JT. (Q-News)

**

Break 1

From the United States of America, We are the Amateur Radio Newsline, heard on bulletin stations around the world including the CARES repeater on 146.73 MHz and serving Gulfport Mississippi.

(5 sec pause here)

**

ENFORCEMENT: THAT CHARGE SHOULD NEVER HAVE BEEN FILED

The FCC has told a Midway, Tennessee ham that his complaint about a club repeater has no basis in fact:

--

Hollingsworth: “We dismissed a complaint filed by Jeffrey Bible, K4MFD, of Midway Tenneseee. His complaint was against the Andrew Johnson Radio Club repeater W4WC which is located on an adjacent tower.”

“We found that despite allegations, the W4WC repeater had not lost coordination just because of a move. The move was within the coordinators limits. In fact, the repeaters have been operating for years with no problems.”

--

That was the FCC’s Riley Hollingsworth, K4ZDH who also says that both parties are coordinated, so both will have to work together to solve any interference that might arise. (FCC, RAIN)

**

ENFORCEMENT: FCC REFUSES TO INTERVENE IN ATV REPEATER DISPUTE

The FCC has also declined to intervene in a dispute involving two Mid-West Amateur Television repeaters. One owned by a major radio club and the other by an individual. The main reason. There is no coordination for ATV in the area. The FCC’s Riley Hollingsworth explains:

--

Hollingsworth: We notified Adrian Oaks, KB8GRJ, of Xenia Ohio that we would not get involved in a dispute that he has with the Dayton amateur Radio Association over the operation of an ATV repeater. Dayton’s repeater, W8BI, has started occasionally operating on frequencies registered to Oaks. I emphasize registered nor coordinated. There is no coordination program there for ATV repeaters. But there’s no showing of actual interference.”

“DARA uses it for 20 to 45 minutes a week. It makes the repeater codes available to all so that anyone receiving interference can shut off the repeater. It is (also) willing to adjust operating times to accommodate other ATV users.”
--

Hollingswoth says that there is no real conflict and therefore the situation does not warrant any FCC enforcement action. (FCC, RAIN)

**

ENFORCEMENT: PRE OPERATION LEADS TO LICENSE SETASIDE

The FCC has told a newly licensed ham that his license grant has been set aside. In a letter to John A Green, KG4RFI, of Mobile Alabama, the commission says that it has information which indicates that he operated on the W4IAX repeater and was also heard at various times on repeaters on 146.685 and 147.090 MHz in the Baldwin County area. The FCC says that all of these transmissions were made during a time that Green did not hold am Amateur service license.

Green was given twenty days from the date of the FCC letter to him to write back and explain certain issues. This includes any instances between the cancellation of his General Class license on September 14, 2001 and the grant of his Technician Class license on January 24, 2002 in which he operated any Amateur Radio transmitting equipment. (FCC)

**

BAMES IN THE NEWS: KD7DDG LOOSES AZ MAYORAL RACE

A follow-up to the story of Tim Weaver, KD7DDG, who was running for the office of Mayor of Glendale Arizona. Well, the votes have been counted and Weaver was not successful in his bid to oust the eight year incumbent Mayor who had the backing of the firefighters union.

The count showed that Weaver had polled only about 24% of the votes needed. Weaver says that the results were disappointing, but respectable for someone outspent and out-volunteered. (RAIN)

**

NAMES IN THE NEWS: RAIN CONTINUES CLEGG RETROSPECTIVE

Hap Holly, KC9RP tells ius that this weeks RAIN Report is part two of a retrospective look at famed ham radio pioneer Edward T. Clegg, W8LOY. This as seen through the eyes of his son-in-law Rob Mc Guffie, K2HZN. Its on line right now in digital streaming audio at www.rainreport.com or analog telephone audio at 827-847-7246. (RAIN)

**

NAMES IN THE NEWS: N9RLA FIRST CENTRAL DIVISION ROVER CERTIFICATE

Some names in the news. First is Dan Evans, N9RLA, who has taken first place as a rover station in the ARRL Central Division. This in the June 2001 VHF contest. Dan is from Scottsburg Indiana. (VHF Reflector)

**

NAMES IN THE NEWS: K8JAC NAMED KANAWHA HAM OF THE YEAR

Also, congratulations to Amateur Radio Newsline's own Jeff Clark, K8JAC. This, after being named Kanawha Valley Amateur Radio Operator of the Year 2002.

A ham since 1981, Clark's Amateur Radio volunteer activities include the post of Emergency Coordinator of Kanawha County, West Virginia. He is also Publicity Director of the Kanawha Amateur Radio Club, editor of the clubs newsletter and technical coordinator of the W8GK repeater. But thats not all. The local ARES group, which Clark coordinates receives high marks from county officials and is often called on to provide communications during civic events and emergencies.

Clark received his award on Saturday, March 16th at Charleston Hamfest. Another Amateur Radio Newsline anchor, Jim Damron, N8TMW, had the honor of making the presentation to K8JAC. (ARNewsline(tm))

**

NAMES IN THE NEWS: WA6ITF TO SPEAK IN JOPLIN MO

Amateur Radio Newsline producer Bill Pasternak, WA6ITF, will be the featured banquet speaker on Saturday April 13th at the Joplin Hamfest. The venue is the John Q. Hammon Trade Center in Joplin Missouri.

Situated about halfway between Tulsa Oklahoma and Kansas City, the Joplin Hamfest is a 200+ table event. It also features spacious parking with easy access, wide aisles, forums, ham radio testing and prizes.

Interested? More information is on the web at www.joplin-arc.org. (ARNewsline(tm))

**

BREAK 2

Here when you need us 52 weeks a year. We are the Amateur Radio Newsline, with links to the world from our only official website at www.arnewsline.org.

(5 sec pause here)

**

ANNIVERSARY: HAPPY 20TH ANNIVERSARY HEIL SOUND

This week marks the 20th anniversary of a very special company. We are talking about Heil Sound Limited. And when you talk about Heil Sound, you are really talking about its founder Bob Heil, K9EID.

Over the years, Bob Heil has been an audio consultant, an inventor, a musician and lots more. Looking back, He says that everything harkens back to his first love. His hobby. Amateur Radio:

--

Heil: "It's been an incredible ride from a little kid playing pipe organ in the Fox (theater)n through playing with my Harvey-Wells and SX-99 which I still have, and understanding what it took to make all of these things.

“Then I started building different transmitters and then started building sound equipment.”

“We actually changed the world. We are the guys that figured out how you stack and hang speakers. Why? Because I could set up a Rohn 25G (tower) and hang speakers higher than anybody else because of my ham radio.”

--

After years of touring with such number one acts as the Eagles, Bob decided to give something back to the hobby that had lead to his success. Thats how Heil Sound Limited was born.

--
Heil: My life has evolved around 45 years of being K9EID, and I will always be so grateful to everybody in this hobby for allowing me to do my thing and along the way to help someone. Thats the bottom line that we are able to help somebody and it makes me real happy to be able to do that.”
--

Bob is now celebrating the beginning of the company’s third decade with a number of new and innovative products for every aspect of ham radio voice operations. You will get to see all of them in a few weeks and meet Bob in person at Hamvention 2002. (ARNewsline(tm))

**

HANDI HAMS: E-NEWSLETTER MAILING CHANGE

The Handi Hams says that it is changing the way in which the groups weekly e-letter is being distributed in HTML format. According to Handi Hams Pat Tice, WAZ0TDA, constant barrages of virus threats to Microsoft Outlook makes it risky to continue maintaining the HTML list in Microsoft Outlook. So the group is moving its list to a mailer called Group Mail. This says Tice will be bring with it minimal risk of sending a virus to the group of HTML subscribers. The text subscribers continue to receive the e-letter through Yahoo Groups. (HandiHams)

**

EVENTS: 2002 WEAK SIGNAL BANQUET

Tom Whitted, WA8WZG, reports over the VHF Reflector that tickets are now on sale for the 10th annual Weak Signal Banquet. This year the gathering will again be held in Dayton Ohio on Hamvention weekend. If you are interested in attending, more information is in cyberspace at www.wa8wzg.com. (VHF Reflector)

**

INTERNATIONAL - CANADA: RAC SM ELECTION RESULTS

From our neighbors to the North comes word that Tom Caithness, VE1GT is the interim Section Manager for Canada’s Maritime Provences. He was elected for a two-year term, which began March 1st.

Also, Derek Hay, VE4HAY was recently re-elected Section Manager in the Manitoba for a two-year term snd Joe Craig, VO1NA has been re-elected Section Manager for the Newfoundland and Labrador Section for a two-year term. Both take office on July 1st.

All three ran unopposed in their respective Radio Amateurs of Canada sections. This eliminated the need for a balloted election. (RAC)

**

DX

In D-X, the big story is of coarse Ducie Island. The VP6DI team came on the air on March 17th and its was bedlam. Take a listen.

--
audio here
--

Ducie Island is a small, uninhabited atoll in the South Pacific and is part of the Pitcarin Island chain. It is also among the rarest DXCC entities in the world as proven by the recording you just heard. It was made in Australia by VK4DX using a Kenwood TS-570D transceiver and posted to his contest website. (Audio courtesy VK4DX)

**

THAT FINAL ITEM: ARDF CHAMPIONSHIPS IN ATLANTA

And finally this week, the calendar says that its spring and hams around the country are turning to outdoor activities such as new antennas and hidden transmitter hunting. Here's your chance to prove you're the best at the latter activity, as Newsline's Joe Moell K0OV explains:

--

The biggest annual event in on-foot hidden transmitter hunting is early this year, so time is getting short if you want to take part.

The Second USA ARDF Championships will be April 19-21 at Franklin Roosevelt State Park near Pine Mountain, Georgia. That's about 70 miles southwest of the Atlanta airport. No matter what your level of skill or experience at radio-orienteering, you'll be welcome. Experts will be vying for positions on Team USA as it travels to Slovakia for the World Championships later this year. Beginners will be picking up the best RDF techniques from these experts, and learning how to put on similar events in their home towns.

The official deadline to register for the national championships is April 6, but Georgia Orienteering Club urges you to let them know you're coming by March 29, so they can plan food for the picnic supper on Friday and the spaghetti dinner on Saturday.

Learn more about what it's like to be in the ARDF Championships by reading about last year's event in the March issue of QST, and in December and January's issues of 73 Magazine. There's lots more on the subject at my Web site -- www.homingin.com -- plus a link to the registration site for the Pine

Mountain events. That's homingin -- one word -- homingin.com

From sunny southern California, where we're soon having our third practice session of the year to get ready for the championships, this is Joe Moell K-zero-Oscar-Victor for Amateur Radio Newsline.

--

Again, that website is www.homingin.com (K0OV)

**

NEWSCAST CLOSE

> (The classic ADF question.)
>

I recall a radar direction finder that used four stationary directional antennas (basically just four waveguide feed horns) pointing In four different directions . The bearing to the signal was derived by comparing the signal strength of the four antennas. If you divided your sandwich box into 3 or 4 different compartments with metal shields and put an antenna in each section you might be able to rig up something similar for the AM broadcast band. Perhaps using ferrite coil antennas?

No, a ham named Floyd Everett invented an antenna he calls the Jacobs
Ladder. I found a site about it by doing a search for "Jacobs Ladder
Antenna".

How about 8.60" wide, 1.75" tall, 16.60" long ? Slightly bigger than a sandwich box, but not by very much.

Dear Cec,

You have my heart-felt sympathies about your garden.

As you may know, when I changed my mode of living some years back and returned to the same garden I played in 65 or so years ago and made use of the same poles, still standing without any preservatives my father first made use of, I began ploughing it up, yard by yard, in order to insert shallow-buried radials.

I suppose, on average, over the years, there has been an increase in received signal level of something less than an S-unit. What the improvement might have been in the reverse direction has always been uncertain. S-meter reports via QSL cards have never been renouned for their accuracy.

The end result, you may be pleased to hear, insofar as the garden is concerned has been beneficial. It has returned, all of its own volition, to a nature wild-life reserve. A miniature Safari Park.

There are creatures now living in it I never knew existed 65 years back when the countryside had already been poluted by 150 years of coal mines, blast furnaces, steam hammers and steel nuts, bolts and washers. I now have toads, foxes, squirels, hedgehogs, wood-lice, un-named birds plus some creepy-crawlies which could have originated only in outer space.

All of which I'm certain are grateful for my idle laziness and neglect to use weedkillers in my small patch of land. None of my neighbours have ever complained about the clouds of dandelion seeds which float from my garden on to theirs in September. Neither have they ever complained about the wierd contraptions which loom over my house and fence, appear and disappear every 12 months or so.

People round here, the not-so-long-ago descendents of young mothers who carried their babies on their backs down the coal mines to earn a half-penny an hour for a crust of bread, are most accommodating and understanding. There's been only one case of TVI and a choke in the downlead in this neighbourhood in the last 76 years.

So there you are Cecil. Scatter some weeds. Allow your back yard to revert to nature. Hang up your 45 in its beautifully polished pigskin leather holster and make friends with the rattlers. Your DX cannot but improve with time.

Jim Weir wrote:
"If the can can rotate vertically----how can I tell---where the signal is coming from?"

This seems to be the case of a fixed loop on a conveyance which can be pointed in any direction, and the loop is capable of broadcast reception.

Maybe I don`t understand the question because I think the standard ancient solution fits this problem. A loop though ever so small has sharp nulls on its axis. The ambiguity of not knowing if you are coming or going is solved with a stationary sense antenna.

If the system has to be very tiny to avoid drag, you may need very high gain and very low noise indeed. Aren`t there composite materials which are electrically transparent and extremely strong so that a salient loop assembly would not be required?

If external antennas are yet needed, why not use a tiny yagi working with UHF TV broadcasts?

Why hasn`t the global positioning systems made all the other systems obsolete?

When I fly across the oceans, the position of the aircraft is constantly displayed on on an LCD color screen map with the current position pinpointed for the amusement of the passengers. This isn`t determined from tuning in low and medium frequency stations, surely.

Best regards, Richard Harrison, KB5WZI

Jim,
The two orthogonal loops, with ferrite cores of course, are sufficient if the carrier phase relationship can be observed. As one turns the loop through null the phase reverses. It's been done in Omega receivers where a sense antenna is impossible. This one is probably best with some DSP but conceptually I'll try to give a picture. Think of separate receivers for each antenna but each receiver is a direct conversion quadrature receiver. A quadrature receiver uses two mixers with the LOs having a 90 degree phase shift in this case the LOs are shared between the two receivers. The carrier magnitude is the sum of the squares of the outputs of each receiver. Bearing +or-180 degrees can be computed from the magnitudes and the 180 degree ambiguity resolved by looking at phase which is why the complex demodulation. The phase of one carrier relative to the local oscillator is arc tan (out1/out2) where out1 is the mixer with the reference LO and out2 is the output of the mixer with the 90 degree phase shift.
Quatrature direct conversion receivers are frequently used as FSK pager receivers and some implementations use a single LO but a 90 degree phase shift in the input channel..

Regards
Jerry

Excuse me, sir, and I mean no offense because I know you were simply trying to help.

Showing me some hardware that ostensibly does what I am trying to do is fairly useless UNLESS you can explain what is hidden inside the potted antenna AND how they are using what is inside the antenna to do the job. King/Bendix has had a combined sense/loop antenna for twenty years, but unless we can come to some understanding of WHAT the technology is and HOW it is doing the job, simple references to another commercial product are worthless.

I'm not an "of course" kind of guy. I fail to understand the necessity for ferrite in the core of the loops other than to concentrate the magnetic field, which will be there, ferrite or no.

are sufficient if
> the carrier phase relationship can be observed.

So are we saying that simple measurement of carrier phase relationship of two orthogonal loops are sufficient to determine bearing? I can't resolve the 180° ambiguity in my brain. Help me here. Seems to me that you can tell direction with an ambiguity, but it requires a third antenna to resolve the fore-aft problem.

As one turns the loop through
> null the phase reverses.

With a fixed antenna, one cannot turn the loop without turning the aluminum can, which was part of the "can't do" criteria of the original problem. And no, the phase doesn't reverse, it goes through an instantaneous shift from zero to 360°, which is the same phase.

Think of separate receivers for each antenna but
> each receiver is a direct conversion quadrature receiver. A quadrature receiver
> uses two mixers with the LOs having a 90 degree phase shift

That's fine for spot frequency. However, as you tune across the band, the LO phase shifter cannot track a constant 90° shift.

Forgive me. I'm dense. I'm an analog cat in a room full of digital rocking chairs. Treat me kindly.

Jim

Jim,

The ferrite (while not absolutely necessary) is to make the physical loop smaller, it has the effect of multiplying the loop area by the permeability of the core, a result that I could not find in any literature but have proven experimentally and analytically.

Roy, my references limit the use of the term "sky wave" to signals refracted
by the ionosphere, ie what we commonly call "skip".

The space wave is any signal taking the direct line of sight path, or variations
such as signals reflected off of terrestrial obstacles, or directed by various
tropospheric bending and ducting phenomena.

The ground wave is the signal coupled into the air/ground interface. It follows
terrain contours much the same way as a signal propagates along a G-line.

At most points inside groundwave range, the signal at the receiver is a
mixture of the space wave and the groundwave signals. At the edge of
the first skip zone, the skywave is added to the mix. This results in a
number of multipath fading situations, not easily modeled in detail.

Jim,
Sorry I didn't finish the comments.
Remember the field theory of magnetic induction, the right hand rule for a moving (or time varying) magnetic field inducing a voltage in a conductor. The phase is 180 degrees different if the signal comes from aft instead of from for. Rotating the loop was to help under stand the phase shift. not part of the solution.
The 90 degree phase shift can easily be maintained with a digitally derived LO. That's part of why some DSP would help. Think of a counter addressing a table containing a sin function and the same counter addressing a cosine table. (not the best way but easy to visualize) and the output each of the tables goes to a DAC.

Well, such 'leads' are never worthless...

Although I'm familiar with the ARN-194 product from my work, let's see what information is publically available on the Internut.

First browse the R-C website, not much else there...

I wonder if this sort of technology is patented ?
www.uspto.gov
Select search collection <Patents>
Click on <Advanced search>
Enter: 'ttl/direction and ttl/finding' (ttl = title)
Uh oh... 137 hits - that's too many... let's add R-C
Enter: ttl/direction and ttl/finding and an/rockwell (where an=assignee)
Bingo !
Hit #5 is:

Patent # 3,967,280, "Direction finding system with integrated loop and sense antenna assembly", filed: June 29, 1976 (must be expired by now ?).
Assigned to Rockwell.

You can find this patent directly on:
http://patft.uspto.gov/netahtml/srchnum.htm
Enter: '3967280'
It is all laid out, chapter and verse. The images are .tiff and you might need a plug-in to view them. For some reason, my PC is using the QuickTime plug-in to view them. Your mileage may vary...

Sorry it took so long...I had to give my son a bath in the middle of this...

Jim,
The method I've described works whenever there is an output from both recievers it fails at each of the 4 nulls but tracking and remembering the bearing during those nulls in a moving can shouldn't be a problem. To help see that it's a 180 degree phase change as a loop is rotated thru null consider an air core transformer that allows one winding to be rotated about an axis perpendicular to it's axis. The phase between the windings certainly isn't the same either side of null unless we swap leads as we rotate thru null. The H field from that transmitter is no different than the field of the hypothetical transformer.

Regards
Jerry

Length of a dipole is on the technician exam. In any case, you think that knowing Morse code (at a higher rate, it is still required) would some how make people more capable of building antennas?

I read in sci.electronics.design that Jim Weir <jim@rst-engr.com> wrote
(in <u9qnqu2e3ndrb2@corp.supernews.com>) about 'Direction finding', on
Sat, 23 Mar 2002:
>That's fine for spot frequency. However, as you tune across the band, the
>LO phase shifter cannot track a constant 90ï¿½ shift.

There are several analogue ways of achieving that; broadband 90 degree
phase network, PLL and no doubt other that I don't recall at present. It
can also be done digitally, and mixers accept square waves quite
happily.

Doc, W5LZ wrote:
"---he only wanted to match a loop to a 50-ohm impedance."

Doc may have missed the first chapter of this story. Cris is trying to build a broadcast station. He asked how it is done in a previous posting, and in this posting asks how to match a loop to 50-ohms at 1.5 MHz.

At 1.5 MHz, a loop is almost surely the wrong transmitting antenna because of propagation at that frequency. Only ground waves propagate during daylight hours. A horizontal loop launches horizontally polarized waves which do not propage by ground wave. The sea or good soil shorts them out. So, a horizontal loop is no good in the daytime on 1.5 MHz.

A vertical loop, if it is fed at the right place, can launch vertically polarized waves which will propagate at 1.5 mhz during daylight hours. The only vertical loop which is non-directional is compressed into the equivalent of a folded dipole. A simple vertical mast is less problematic and a better bargain. That is why all broadcasters use them.

Best regards, Richard Harrison, KB5WZI

5560. Suggest coax for long run

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-24 14:33:38 UTC
From: monte.carroll@nashville.com
Message-ID: <3c9dd933.260709152@news.nashville.com>
Source record: 146248

Good morning ladies and gentlemen. The tower is about ready to tilt up and mount, and I need some coax to run from the shack to the antennas - probably around 150 feet.

There will be two runs. One is from a 100 watt HF rig to a G5RV. The other is for a 6 watt 2-meter HT (may upgrade to a 50 watt unit later) to a J-pole. They will travel out of my 3rd story shack, down to the first level, across to the garage, over the garage roof to the tower.

What is your suggestion for coax? I would like the best deal - not necessarily the cheapest or most expensive - for my situation. And where do you recommend I purchase it? Thank you for your efforts.

Two orthogonal ferride rod antennas and a third one offset and
shielded for directionality? No messing about with signal phase, just
strength. Although that might need to be offset by more than the space
available. Might be interesting if you could get hold of a 'Y' shaped
ferrite.

Thinking about this a different way. Given that you have even a vague
idea of where you are, could you not just use 2 orthogonal ferrite
antennas and take readings from several AM transmitters? This would
need information regarding the relative location of the transmitters
maybe, but you would need that for position fixing anyway.

It appears to be a j-pole that's been finagelled to broadband it over the whole two-meter band. I just wonder, though, if in the finagelling, you lose a little power.

Not if you are good at doing some world-class websurfing, as you obviously are. My hat is off to you, sir, and I apologize for using "worthless" in the text.

> You can find this patent directly on:
> http://patft.uspto.gov/netahtml/srchnum.htm
> Enter: '3967280'

Precisely correct. And exactly what I was looking for. The idea of using active devices to take the hi-z loop and transforming it into something that will drive a low-z cable isn't new, but I'm surprised that as late as 1975 that they could patent such a device. Even with the drawings and explanations, though, the sense antenna remains somewhat of a mystery. Any further leads on this?

> It is all laid out, chapter and verse. The images are .tiff and you might
> need a plug-in to view them.

Yes, I did, but the patent office webmaster really has it all together. They even specify the version of TIFF you need and point you to a free plugin.

IF you are willing to accept the accompanying losses, preferring the convenience of smaller cable
sizes, some of the newer "mini-RG8" probabbly is a better choice than RG-58... Seems a shame tho'
with the obvious expense and effort spent on the REST of the installation, to then compromise the
function of the system by use of lossy, inefficient feedlines...

For a good online source of various feedlines and accessories, see:

http://www.cablexperts.com

Hard to beat BuryFlex from DavisRF

http://www.davisrf.com/ham1/coax.htm

The stuff is directly buriable, abrasion resistant, and noncontaminating
as well as having very low loss. And it's relatively cheap. No
financial connection, just a satisfied customer. Oh, and you can use
std PL-259s, no special connectors or tools.

FWIW,
Pete, AD5HD (ex-WB5RKC)

5574. Re: Vertical Antenna Recommendation

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-24 19:19:37 UTC
From: Dust Might <alfaromeodiscovolante@hotmail.com>
Message-ID: <dFpn8.2649$xa5.84593@newsread1.prod.itd.earthlink.net>
Source record: 146262

The band this half-wave antenna will operate on really depends on how much height you have to suspend it from (I have
only used it in a vertical position, or it could be mounted horizonally, I guess). This antenna is 3/4-wl of any
particular band overall, so can be quite long if used on 30, 40 or 75 meters. Having some distance between the earth and
bottom of this antenna is nice too.

As far as using a *tuner* for operation of another band outside of what frequency this antenna would be cut for, well
sure, I guess a tuner can be used to tune nearly any metal object...but no, these antenna's are designed to be used for
the band in which they are cut for.

For a basic understanding and description of its basic design: do a google search of *emergency j-pole or pocket j-pole
antennas*. Most results will yield either a 2 meter or 440mhz antenna constructed entirely out of 300 twin-lead wire;
whereas the one's I build for hf are constructed using 16-gauge electrician's coated (black for stealth) wire for the
top 1/2-wl portion attached to 450-ohm ladder-line for the 1/4-wl portion, finished with a 2-foot section of rg-58
coming down the bottom attached with wireties (to the ladder-line).

Earlier, someone mentioned incorporating the *Franklin Array* or Raser antenna design within this style (described
above) for increased gain, but I am still reading up on those arrays....Mighty Interesting, though!

> ...world-class websurfing...

<blush...> I knew that those wasted years would someday pay-off... <grin>.

> Even with the drawings and explanations, though,
> the sense antenna remains somewhat of a mystery.
> Any further leads on this?

The sense antenna appears to be 'nothing special'... It is item #41.

Extract from the text of Patent # 3,967,280:

"A Fiberglass cover 60 of streamlined configuration might enclose the assembly, with a conductive material or screen wire sense antenna element 41 carried on, or embedded in, the Fiberglass cover 60. Sense antenna 41 is connected by a single interconnection 57 to the electronic circuit card 63. <snip> Because of the reduced height configuration and capacitance requirement for the sense antenna made possible by the present invention, the comparatively small area sense antenna depicted in FIG. 5 provides the same sensitivity as heretofore-employed sense antennas..."

It seems that the sense antenna is simply a chunk of screen embedded in the cover and connected to a preamplifier by way of a single wire. 'Nobody home' so to speak (meaning nothing complicated). Sort of an 'active antenna' like the Sony AN-1 and others; it's all in the preamplifier. The antenna itself is just 'coat hanger' technology.

You thinking of building one ? Keep in mind that the actual ARN-149 product itself has internal "Quadrantal Error Correction (QEC) set by aircraft connector strapping, eliminating corrector modules and airframe-specific internal adjustments..." The patent barely mentions the topic.

One might have thought that the patent application would have contained dimensions for a "suitable" sense antenna, but then again, that's what tinsnips are for.

> assembly, with a conductive material or screen wire sense antenna element
41
> carried on, or embedded in, the Fiberglass cover 60.

Yes, I'm going to build one, the only question is time. I've got two other projects ahead of it, but it will get done. As to the error correction, I'll build one and see what kind of errors I get. The specifications for high-end military and low-end civilian vary several orders of magnitude.

First thought is to wind two toroids and mount them at right angles to each other and glued onto a blank piece of PC board, with the sense antenna just a patch of copper at the far end of the board. The nice thing about doing stuff down at a MHz. or so is that you can actually examine the signals out of the antennas with a fairly low-tech scope to determine phase angles and the like. The shop is about three blocks from a saturation radiation source at 830 kHz. transmitting 10 kW continuously. First time I've ever intentionally USED the sucker; heretofore it has been a royal pain to keep it out of the workings.

Source record: 146119

Evan -- too many variables -- we need to know can u put in ground radials, can you put a vertical up and use elavated radials, do you have to have a 1/2 wave radialess antenna. That sed;
maybe start with "Dirty Little Vertical Antenna Secrets" by Butternut.
http://www.bencher.com/pdf_download.html

Then go to eHam.net and read what users think of their 1/2 wave end fed radialess verticals (Cushcraft R-7000, R-6000, R7, R5, R8), (Force 12 Sigma-5 vertical dipole), (Hy-Gain DX77), others.
http://www.eham.net/reviews/products/13

FYI: I have an R-7000 Cushcraft and have worked a ton of DX (Brag Brag). Only because I have HOA and CC&R's
otherwise I'd have a tower and a TH7DXX beam -- you betcha.

Evening Chris and the gang...

I built this antenna today and was very impressed with it. I also found out by accident that it makes an excellant 17 meter antenna when you forget to connect the point where they say to trim it. The SWR was 2.1:1, but it REALLY out did my dipole. I worked PJ2/DL7UFR on it, and tested both the Dipole and the loop and the loop seemed to work quite well.

One of the good things about toroid inductors is the fact that their
external magnetic fields are orders of magnitude lower than solenoid wound
inductors. Their magnetic field is almost totally contained within the core.

That good point about toroids means that they make very poor antennas.
A good transmitting antenna is also a good receiving antenna. If a device
doesn't radiate much, it won't receive much either.

Source record: 146133

I have been using one mobile since the IC735 was new.
It has never failed and works.
It also works very well fixed mobil with an extra piece of wire clipped
to the tip of the whip and thrown up into the trees or bushes.

As a mobile in motion, it it is not as efficient on 40 as a good
screwdriver or Texas bugcatcher.

Some of the newer designs with frequency memory and latching relays
would be nicer to use.

Aloha,
John KH7T

I have a Radio Shack Pro-89 scanner.
It has exactly 0.00 Volts at the antenna terminal when on.
Now, My Icom IC2000H may have more than that on the antenna terminal when in transmit mode, But I'm not going to try measuring it with my DVM...

What you have does sound like either a Helix antenna or simply a coil...

5597. Difference bt 1/4 & 5/8 mobile HF

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-25 10:24:19 UTC
From: post_to_usenet@hotmail.com
Message-ID: <b6b4e772.0203250224.79645124@posting.google.com>
Source record: 146135

Hi,

I would like to know/understand why, for a mobile antenna, 1/4 is any different from 5/8 (or even from a tuned screwdriver antenna). As I see it, and as long as neither is center nor top loaded, the radiating element is the same for both (considering that both use the same whip length, ex.: 5~7 ft. for 10m), so my reasoning is that whatever the matching network, the radiation pattern will be the same, only network looses will be different.

In fact, I don't uderstand very well how a less than 1/4 physical length whip + adaptor base may be sold as 5/8, whatever there is in the matching network.

Please explain if this is correct or not.

TIA for responses

Toni

5598. ATU for magnetic loop antenna

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-25 13:40:35 UTC
From: Fabio Morsani <fabio.morsani@pi.infn.it>
Message-ID: <3C9F28D3.33EC16AD@pi.infn.it>
Source record: 146136

I developed an automatic tuner for my homebrew magnetic loop antenna.
It allows the user to directly enter the desired freq using a 4x4
keyboard, then the ATU tunes the loop at that freq for minimum SWR.
Alternatively (preferred), you can just press a key and the ATU reads
automatically the current RTX freq (for my TS130, it reads the local
oscillator freq and subtract the IF value) then performs the tuning.
More, the keyer and the mic pass through the ATU, which allows the
PTT (used for CW also) to be asserted to the RTX only if the current
SWR is below a programmed limit ... and other features.

I successfully used such a ATU for some years.
Recently I developed a serial interface to connect the ATU to
the CAT port of some commercial RTXs (ICOM, FT1000, TS850 ...).

I'd like to know if someone has built something of similar, his
experience, some ideas to improve it.

On my site http://dai5lhy.dadacasa.supereva.it/
you can find some info (for the moment in italian only).

5599. Re: Difference bt 1/4 & 5/8 mobile HF

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-25 14:22:34 UTC
From: 'Doc <w5lz@icok.net>
Message-ID: <3C9F329A.D7913CE5@icok.net>
Source record: 146137

Toni,
An antenna's physical length isn't necessarily it's electrical length. An antenna shorter than 1/4 wave length can be made an 'electrical' 1/4 wave lenth by adding a inductance in the form of a 'loading' coil. This 'loading' coil can be at the base, the center, or the top of the antenna. By judiciously picking the value of inductance, the size of the coil, an antenna can be made to 'appear' to be almost any portion of a wave length, or multiples of a wave length, to an RF signal.
An impedance matching circuit can be either inductive (using a coil) or capacitive (using a capacitor). If it's inductive, the same coil can be combined with a loading coil on a base loaded antenna. Again, depending on the size of the loading coil, a base loaded antenna can look quite a bit shorter than it's electrical length, even if an impedance matching coil is present. Usually, the loading and matching coil is encapsulated, so you can't tell what the antenna's electrical length by the length of it's whip.
Discounting the other things that affect the radiation pattern, an antenna's electrical length determines the shape of it's radiation pattern, not the antenna's physical length.

Monte,

<http://www.therfc.com/coax.htm> lists various cables and has links to tables that show their loss per 100 ft at different frequencies. You will find that RG-8 is OK for HF but 150 feet of it will eat up half your power and more at 2 meters and is mucho worse above that. I'd go with RG-8 for the HF cable but spring for something like LMR-400 to drive the J-pole. Since loss is "per foot" short lengths of RG-58 or better yet RG-58 foam (RG-8X) are OK for short runs. My 2 cents.

You might consider scrounging up some CATV hardline. Generally short lengths
are free for the taking and connectors can be home brewed from plumbing
fittings. Some times two-way shops have some 50 ohm stuff around, too. I
find the 75/50 ohm mismatch is easily ignored, even up to 5 gHz.

>
> For this type of antenna he would like to know:
>
> (1) what is the directional pattern?

It barely has one. The pattern is like a racetrack with max gain
broadside to the horizontal wire.
> (2) what are the typical gain figures?

According to Eznec about 1.7-1.8 dbi or so. So like doc said, for all
practical purposes it's fairly omnidirectional. But it does have a tad
bit of gain broadside using DBI as the reference. You might notice
this a little bit on fairly close in stations as that gain comes from
the horizontal wire. Fairly high angle ...And you have to consider the
wavelength above ground for the horizontal wire. If the wire were
high, some of that radiation will be at low angles. If low , probably
not. DX at low angles? I doubt much difference at all in any direction
as most of that radiation will be produced by the vertical section.
Not as much as a 1/4 wave L though. The half wave L does have a good
bit of high angle radiation from the horizontal wire. There is no
overhead null. The maximum gain is nearly overhead. About 100 degrees.
OK for close in, but a compromise for dx. For average close in work on
75m, a dipole would be much better. I'm not sure what he's using it
for.. MK

> the antenna?

Your 100ft of RG58 and 50ft of RG8 at 146 and some assumptions: VSWR 1.2 at antenna, 2W out from the HT yeilds 350mW at the antenna (only 17% of the available RF was delivered to the antenna).

VSWR will look pretty good at the HT (1.03), so that would please some.

Your feedlines is losing most of the the likely improvement of the otherwise pretty serious antenna installation.

Even if you use RG8 or like for the whole run, you won't like the answers at 2m (40% of the available power delivered to the antenna).

>
> I would prefer to have small cable in the shack for ease of
> manipulation.

Yes, it is convenient... but if you use a low loss cable for the bulk of the run (eg LDF4-50A for 150ft on 2m), then a 10ft tail of RG58 would contribute one third of your system loss.

Could anyone oblige with a URL of AutoCAD libraries of Aerials, Aerial mountings e.t.c. or know of any shareware of. Libraries of marineMarine electronics

Perhaps aerial manufacturers like Andrew(s?) can supply these libraries.

These might be used in workpacks (construction, general arrangement, schematic, as built type drawings) for prospective future Comms package installation projects. Also would be useful for when I apply for planning permission for a couple of aerials at home.

I'm hopefully moving back into RF systems (from Multiservice and datacomms) so I'm tooling up with new PMS system, knowledge, methods and drawing libraries.

Are there standard representations for radio diagrams in the vain of BS3939 for instance?

Hello Richard,

If you are really interested in reading a good book on Nikola Tesla, try Margaret Cheney's book, "Tesla...Man out of Time". She also co-authors another book with Robert Uth called, "Tesla...Mater of Lightening". By the way, PBS had a one hour program based on this book also. "My Inventions", his autobiography is available through B&N also, as are all these books.

Ken Burns, the documentary film maker, made a 2 hour film entitled , "Men who Discovered Radio". I have nothing but praise for all of the Burns' brothers films, but I was incensed that throughout the two hours of this show, not once was Tesla's name mentioned! Despite the fact that eight months after Tesla's death, the United States Supreme Court concluded that he, Nikola Tesla, and not Marconi, was the inventor of the radio. Other than this grave omission, the Burns video is quite an earful(!) and very well done.

Had a Titan up since 1997, guyed. Survived wind storms, one tornado and
Wisconsin winters. Poor on 75/80 but works fine for me on the other bands.

Check a good deal of info. available on the NJ QRP Club site....

http://www.njqrp.org link on left side of page...

I would believe your battery theory except for the fact that this phone has
not been able to link to the tower since the day I got it out of the box.
Also I know of another guy who had a big improvement on his phone.

The idea that these CB knockoff antennas perform as a 5/8 is pure
marketing.
If they were full length there is a difference as the out of phase portion
of the 5/8 antenna flattens the main lobe resulting in a bit more gain.

I had a good laugh on this one too, but I also remember that
when I was just a kid and didn't know much about any of this
stuff I was asking similar questions. Even at age 60 I am
still
trying to figure antennas out!! The terrible thing is that
if
I hooked it up to a short wave receiver I would likely hear
something better -- just as if I had put a hunk of wire on
the
end. My first real experiences with antennas were hooking
my
homebrewed crystal sets to various metallic things and
discovering
that they worked!! I'm still smiling thinking about this
dish
one though!

What happens if you remove the battery, remove the booster, and replace
the battery?

Maybe the lunatics that design the cell phones have an interest in the 'stick-on booster' companies.

Therefore, the cell phones don't have an antenna at all, they just have one-half of a coupling circuit. You have to buy the internal antenna separately and stick it in between the phone and battery. If you don't buy the aftermarket internal antenna, then you have to make do with just the leakage from the coupling circuit (poor match to free space).

Cell Phone: $nil, sign here.
Antenna (sold separately): $20 plus shipping and handling.

Think about the manufacturing costs and profit levels. A dozen cell phones wouldn't have the profit of one stick-on antenna.

It would explain a lot. ;-)

Monte,
The quick and dirty answer is to look at a coax
'spec' table. Decide how much loss you find acceptible,
then choose a cable that falls in that 'loss' range.
Most places that sell radio 'stuff' sell coax, pick
the one with the 'best' prices. If you find a place
that has prices that are too good to be true, it's
probably too good to be 'true'.
'Doc

The thing is really sticky. I think it would be damaged if I try to pull it
off otherwise I would be glad to do so.
I doubt if the aluminum foil would have any effect. After all, the battery
itself is metal.

I have one of those narrow lakefront lots (50'x850'). I was considering putting up a 1000' or so loop as I have trees in the right places. (35' average height) But in reading I discovered loops work best in the form of a loop. duh What I would be putting up would be more like a folded dipole being only 50' in width. Would it be better to put up a Double Extended Zepp instead? Is there any way to model this? Thanks WB8VTW

Thank you for the reply and for the link. Looks like a purchase of a lot of new coax is in order.

OK, here's another question. How much loss is there in connecting two, maybe three sections of RG-8 for the 2-meter? In other words, maybe one length of 75 feet connected to 35 feet connected to 35 feet for a total length of 145 feet.

If the metal battery does not have any effect then how is a copper trace
on a piece of plastic going to have any effect especially when it is
sandwiched between said metal battery and the metal insides of the cell
phone?

Jim Besselman wrote:
"I found it interesting that in the section on electrical engineering there was a large area devoted to Thomas Edison and no mention of Nikola Tesla."

The phonograph and movies have more sex appeal than polyphase power, induction motors, and alternators. The conspiracy theorists say Edison and GE used gifts and threats to focus attention on their man, Thomas Edison, and exclude Tesla, who sold his patents to Westinghouse.

Best regards, Richard Harrison, KB5WZI

You're pretty determined to waste power on feedline losses, aren't you... 8^)

Stringing the lengths/types of coax you specify thru several added connectors and adaptors will cost
you about half your power at 144 mhz...

C'mon fella - dust off the ol' wallet, and get yourself the RIGHT stuff to finish yer install - the
satisfaction of a job done properly will last MUCH longer than the few dollars you might otherwise
"save"...

I like all that I have heard about these antennas but I have no idea how they work. Are there any antenna books that have these type of antennas listed? With only 2 apparent elements how is this omni directional? How is it fed? Is there any matching network? What is the gain and why? What wavelength are the elements? What if you point this antenna straight up will it work as well and be then vertically polarized? With the two elements so close do they couple with each other? Also I was told that most 6 meter halo's are 'shorter' than 1/2 wavelength is this why the Par is better than a halo. Has anyone compared a 'full-sized halo to the Par? Also how does the Par compare to 'Bigwheel' omni antennas like those made by wimo at www.wimo.com ?

Source record: 146175

I am looking for a commercially made bigwheel antenna for the 6 meter band. Wimo at www.wimo.com makes them only for 2m and 440. Are there any antenna books that have these antennas in them? Where can I find the specs to make one for 6 meters? How long is each of the three spokes? Does it need any kind of matching network? How would a 6 meter bigwheel antenna compare to the Par omniangle 6 meter antenna as far as gain and radiation resistance? Has anyone ever compared any of these two types of antennas side by side (bigwheel vs. omniangle). I have narrowed it down to these types of horizontally polarized 'true' omni directional antennas for my 6 meter work but before I build or purchase one I would like to find out all I can about them. Please lead me to any books or articles that might help.

Either of these would be easy to model with the free EZNEC demo program, available from http://eznec.com. The feedpoint impedance accuracy of the loop wouldn't be too good, especially at higher frequencies, due to the limitations of the demo version, but the pattern and gain would be reasonably accurate, at least at the lower frequencies. The standard version of EZNEC would easily handle the loop.

If you use properly installed connectors and seal the connections extremely well to keep water out, there'll be negligible loss from using multiple sections. Do a search of this newsgroup on https://www.groups.google.com and you'll find a lot of information about sealing connectors.

This is the question we'd all like the answer to. Another poster said he had put the gadget in and taken it out several times and seen the signal improve each time it went in and decrease each time it was removed. So far, no one has reported the results of a test using a piece of aluminum foil. Two postings reporting substantial signal improvement have seemed credible, but I'd still really like to see this with my own eyes before taking the gadget out of the scam category. If it really does improve the signal, I don't have a clue why, and I'd really like to know.

Forget the RG-8 for 2 meters. Use better transmission line.

Also be aware that sometimes the losses in the connectors is as great
or greater than the loss in the coax. It is best to minimize connectors.

That might be somewhat true on 2 meters if using N connectors. But UHF
connectors seem to be rather lossy.

Source record: 146184

Cell phones, with few exceptions, use the chassis as a radiating counterpoise.

When held to the face, some of that radiation is suppressed in the far field, and the detuning is not trivial. Hence there is some loss of gain when compared to free space.

The idea of using the battery pack actively as part of this tuned counterpoise led to these alleged coupling devices. I have tested the two advertised on television and have not been able to replicate the claims. They are not fractal antennas/couplers, as some have publicly stated here on this NG.

Incidentally, in the last two years there have been numerous and repeated allegations that I and/or affiliates have been involved with these devices. This is not correct.

Hi Mark,

I'm a 6m repeater keeper, GB3WX, in the UK.

We have tried various "White-stick" antennas, as we call them, and although quoting significant gains, the polar diagrams left much to be desired, in terms of lobes and angle to the horizontal. Gain is not everything.

What about the Cushcraft AR6 or ARX6

The AR6 is just a halfwave base fed, and the ARX6 is 2 x halfwave, although I'm a bit concerned about the quoted gain. My perceptions is that it's just a pair of "close-spaced" halfwaves in phase, and therefore the max gain will be about 1.9 dBD at best.

We have been using an AR6, for over a year now, it has withstood gales with gusts to 80+ mph and everyone in the group indicated that they were getting a stronger signal from the repeater, when we replaced the original "white-stick" with the simple half wave.

Hopefully, this will be of some use to you.

Cheers
Dave, G3ZXX.

This is only a wild stab:

Remember that the bars on the phone display indicate signal strenght,
not quality. Could putting that little foil trace thiggnie near the
units RF amp or antenna simply be reflecting signals from inside the
phones and they interpret it as an extra bar or two?

Just a wild guess...

Allen

My opinion, Roy, is that the thing ___could___ work.

But it would only work on certain phones. The ads also do not differentiate between PCS (1800 to 1900 MHz), and 800 MHz cellular.

The typical cell phone antenna can be thought of as a dipole consisting of the 'antenna' part and the rest of the phone, or as a ground plane antenna for PCS. It is believable that for certain phones at certain frequencies placing a 'fractal' element at the proper place in the phone could create a directional pattern that would improve coverage. However, you would have to have the right phone on the right frequency and be facing in the proper direction.

As to if it __always__ works, I seriously doubt it.

According to my HP8713 network analyzer, the UHF connector loss (from a pair+ barrell) runs in the 0.2 dB range. Not great for EME but not noticable for terrestrial work.

Once upon a time some crooks began marketing little pinwheels that mounted between your carburettor and engine to "better atomize the fuel" and give huge increases in gas mileage and horsepower. A major motorcycle magazine had them installed at their equivalent of a hamfest and reported a significant gain in both power and economy on the 3-400 mile trip home. Then another magazine bought the devices to do a before & after comparison on a dynamometer. They found gas consumption up and power down about 10% when these "marvels" were installed. This prompted the first rag to duplicate the second's dyno test; but when they tried to remove the devices they found none had ever been installed!! The crooks had taken their $$$ and then their credibility.

The PAR Omni is somewhat longer than a half wave. It is this electrical length combined with the isosceles triangle shape that yields a near perfect omni (within +/- 0.4dB). By elongating either the 2 sides OR the base, one could make its pattern elliptical either front back or side-side like other omnis. But, with the chosen dimensions, it is a near perfect omni.
To the best of my knowledge, this antenna 1st appeared in an RCA Technical note from the 50's. Later, the shape was included in the AO softare modeling package.

Because the antenna is non- resonant a matchbox is required to convert its 11+J90 Z to 50 Ohms. Finally, a current mode balun is built in to ensure that both sides of the antenna are equally illuminated and that the feed does not radiate.
Gain, when integrated over the full 360 degree azimuth circle is about 0.4dB more than traditional shortened 1/2 wave omnis.
Hope this helps.

I think the key words here are "properly installed" connectors. I suggest that properly installing connectors (so as to minimize any impedance bumps and keep the shield coverage uniform) is easier said than done. I admire the nice, uniform connections on coax I buy and I have never been able to as neat a job at home. I either melt the center insulation or end up with erratic soldering of the shield around the connector.

Rick,
No, a tuner isn't (or shouldn't) be necessary with
a screw driver antenna. You will need some methode of
impedance matching, but that's usually provided with
the commercially made screw drivers.
'Doc

It's also possible that the foil trace is acting as a counterpoise
against which the radiating element of the antenna can act. Radio
Shack's HTX-202's had a problem of resulting in ERR-2 errors when
operating with 12 volt batteries... A possible explanation that was
given for this was that at 12 volts, the radio operates at 5 watts
output instead of 1. The inefficient antenna design inherent in
handhelds resulted in RF overload on the radio when operating at 5
watts. There is a mod for this radio that recommends a procedure when
rebuilding the battery packs one add a coiled piece of wire inside the
battery pack, attached to the negative lead of the battery. The
purpose of this is supposed to provide a better counterpoise against
which the antenna can operate...

Sound like this might be a feasible explanation for the cell-phone
antenna booster phenomenon?

This is patently untrue. It is better to minimize connectors simply because
they are a source of water ingress and are obviously less reliable than a
similar length of cable, however, this old wive's tale about loss should be
stopped.

The AR-6 is a well-built, sturdy antenna. The problem
in using it for a repeater is that it has uptilt rather than
downtilt.

Hi Roy,

Remember that this magic "device" is from the same people who bring you the Electronic Cell Phone Shield aka the Wave Scrambler (TM). Works on any phone, will not affect the quality of reception, can also be used on cordless phones, prevents harmful electronic waves entering through the ear. Regularly valued at $39.99, order 2 right now for 12.99 + S&H. [I was unaware that the "harmful" radiation from the phone only emanates through the phone speaker.]

The cell phone booster is even better - works better than a four foot antenna - wow, better than a four foot antenna! Not that there is anything special about a four foot antenna at AMPS or PCS frequencies. They could have said that it works better than a 3,000 foot antenna but no one would have believed them - I guess "better than a four feet antenna" sounds more credible.

WHAT A CROC!

Although, I must shamefully admit that I did buy two of them (for research and demonstration purposes only of course), so add me to the list of suckers who merrily handed over $12.99 + S&H (twice). BTW, the Wave Scrambler was free with the cell phone booster (a time limited offer that was only available right then on the phone - what luck!)

Thanks for the distinction between "sky wave" and "space wave", one I wasn't aware of. Richard Harrison has a Terman reference that speaks of the "ground wave" having two parts, a "surface wave" and a "space wave". I've always seen "ground wave" used just as you've said (including in Terman's _Radio Engineering_), and never like in Richard's reference. So that reference remains puzzling.

Another good thing about the AR-6 is it's quite adjustable for the
freq used.
They also make a 10m version. "AR-10". These are easily homebrewed
also. I've made a few of them for 10m. I use a single turn loop at the
base the same way cushcraft does. The cap made from coax. You can also
improve the low angle performance a bit by adding a decoupling section
below the antenna to reduce the feedline radiation. I used a 1/4 wave
section of coax below the feed to a set of 1/4 wave radials mounted
and grounded to the mast a 1/4 wave below the feedpoint. I tried this
on a 10m version and it did seem to clean it up a tad. But they work
fairly well out of the box with no decoupling. MK

C.C.Crane had something called a Selectenna (or something like that)
that, when placed close to an AM radio, will improve reception.
Perhaps it works something like that.

Nope, that's the beauty of a screwdriver. However, one needs a coil,
cap, or transformer at the base of the screwdriver on 75m and 40m.
The feedpoint impedance of a well-designed screwdriver antenna
system is about 12.5 ohms on 75m.

Don't used RG58 or so-called Mini8.

Too much loss. Maybe you could find some free 1/2-in 75-Ohm hardline from the local cable company. That would be good for 144 MHz if cost is a big factor if IF it was free.

Connectors may prove to be a problem but many hams have fashioned their own versions. See ARRL puiblications.

9913 is good too. Sometimes referred to as "poor man's hardline".

Sound like fun.

Paying 200$ for a dipole will always seem a bit strange to me.
Besides, it's a patented air cooled dummy load for the most part
compared to just a coax or even a tuner/ladder line fed dipole. I'll
never use an antenna with intentional resistance. I've got enough
problems with the resistances I don't invite to the party. MK

I don't have any experience at 2 meters, which is why I said "sometimes".
My experience in UHF starts at 400+ MHz and goes up from there.

There are several factors that can affect the connector loss. One major
one is how good a job was done on the cable/connector. I have seen, with
N connectors at 800 MHz, everything from a bit over 0.25 dB per connector
pair to in excess of 1 dB per pair.

For UHF connectors, I think the greatest problem is that they are not
constant impedance - and it is hard to avoid an impedance bump, even
with a well made up connector.

As you state, this may be irrelevant at 2 meters - it is a problem at
800 MHz.

Source record: 146074

I fully believe this report, as I do the others which have been posted. However, there are too many variables involved to draw any conclusion from the "dead spot" report. But when a person can put the gadget in, see a substantial difference, take it out and see the reverse happen, and repeat several times, all from the same location, it's apparent that it's having some effect. Several theories have been put forth, any of which might provide an explanation. I'd put money on something to do with the gadget acting as a ground plane to provide better coupling to the hand, although I don't see how it could improve significantly on the ground plane already provided by the metal battery cell cases. It's apparent that if it does anything at all, it works only for some models of phones, which is consistent with this sort of phenomenon. And if so, a piece of aluminum foil should work as well. What's certain in my mind is that the explanation in the advertisements is totally bogus. I'm equally certain there's no new or magical principle at work here. But there might be some slight deficiency in the design of some phones that the addition of a ground plane might help. Until I saw the couple of postings giving credible evidence of a noticeable difference, I regarded the gadget as a pure scam. Now I think that in some cases it might possibly be doing something, although absolutely not what the sellers claim, and nothing that can't be done with a piece of aluminum foil. And if it is, I'm curious about what mechanism is involved.

I'll remain very skeptical until I see this for myself, though. In a fringe area or location where multipath is present, moving the phone an inch or two can make a large difference in signal strength. So a person running a test might unwittingly fall prey to the placebo effect and conclude that "on the average" it works better with the gadget in, or might coincidentally position the phone to favor the signal when the gadget is in place. If you're sitting in a null, a tiny change in the environment or antenna pattern can make a large difference in signal strength.

I wonder if 'the military' (a hopeless generalization....) sometimes assumes that their dipole is +2.1dBi (not realizing that it is a dummy dipole), and then they keep finding miracle antennas that provide better gain and efficiency in comparison, but over a narrower frequency range.

Maybe I could interest them in my newly developed antenna - I call it the "dipole".

Source record: 146084

NOW AVAILABLE:

New Program, albeit belated, "TRIODE1.exe"

Program TRIODE1 assists with the design of triode, grounded-cathode, RF power amplifiers from 1 watt to any arbitrary large RF output power. For "anode" Americans can read "plate". For "tube" much of the English-speaking world can read "valve". (For grounded grids another program is needed.)

Tube operating conditions can be selected at 1 degree intervals from Class-A, via Class-AB1 and Class-AB2, to Class-C. In other words from anode current operating angles from 360 degrees down to very high conversion efficiency at 45 degrees.

The program first accepts a manufacturer's basic tube data: Mu = Amplification factor, Perveance which is related to cathode electron emission and equivalent conductance, and alpha, a value which defines the curvature in a tube's current-vs-voltage characteristics. The fraction of cathode current intercepted by the grid, sometimes neglected, is also taken into account. But if one or two parameters are unavailable all is not lost.

The program user can then enter his own operating conditions such as DC anode supply volts, amplitude of grid and anode RF voltages, intrinsic Q of the tank coil, output circuit operating Q and, of course, anode current operating angle and operating frequency. Operating angle is a little known but vital factor which a circuit designer must not neglect. It profoundly effects circuit operation by controlling a tube's internal resistance.

It may not go unnoticed there is no reference in the program as to what the internal resistance of a tube might be. Or to matching an amplifier's internal resistance to its load for the purpose of maximising power delivered to that load.

Computed output data includes DC anode current, DC power input, anode dissipation, conversion efficiency, DC grid current, DC grid bias, grid bias resistor value, grid operating angle, grid dissipation, and grid RF drive power required to satisfy the assumed operating conditions. (A common design feature not covered by the program is deliberate dissipation of RF drive power in a damping resistor to improve operating stability. However this does not effect basic circuit design.)

The output circuit may be either a simple tuned tank circuit with a link coupling to a 50-ohm load, or a Pi-matching circuit. All coil and capacitor component values are computed. It is left to the designer to take parasitic tube and circuit capacitance and inductance into account. For coil dimensions, number of turns etc., refer to program SOLNOID2.

If a user should be unfamiliar with the characteristics of triode electron tubes this program will be found to be of educational value. By hitting one or another key the essential data for two types of tube can be entered ready for experimenting. But a set of anode/grid currents versus anode/grid voltage characteristics of any triode tube is essential.

There is a brief introductory note on each parameter used in the program. It may be of passing interest the basic mathematics are equally applicable to that much later 3-terminal amplifying device - the transistor.

On the other hand, for people who prefer the simple life, program TRIODE1.exe can be used just to calculate L and C values of a Pi-matching network to be used with a 3-500Z or any other power amplifier.

If Terman, Everitt, et-al had had this program available in the 1930's they would have got along much faster. ;o)

Download TRIODE1 from website below in a few seconds. One self-contained binary file only. Not zipped up. No unzipping inconvenience. Run immediately. All in plain English. Old timers can find out where they went wrong.

Here we go again. For those who post things like those below, this is what amateur radio is about. I own and operate a B&W antenna configured as NVIA for 60-75 meters. I also use it for all the other amateur bands up to 6 meters. This antenna does the job I want it to do. Yes it works by burning swr in a 600 ohm resistor but the signal is only down ONE s unit for all that.
Those who want to get every miliwatt into the ether a cut and tuned dipole antenna is the way to go. Remember all other antenna's are a compromise between efficiency and size. The closer an antenna is to a match between the output impedance and the wavelength of the frequency and the space/time to install/cost to obtain.
Anything else is personal choice. I don't look down on you for yours, give me the same.

Yeah, I shouldn't laugh because I was probably doing the same thing when I was 10 years old, too. I remember a little one tube AM radio (legal) transmitter that I took to show and tell in the fourth grade because my 200 foot radius AM radio station was my hobby. We hooked it up to some kid's braces to test it. No, he didn't get a shock or anything (good thing he wasn't grounded anywhere) but everyone thought that it was cool because we were transmitting out of Joe's mouth!

My dad was an EE and had built a few radio stations but he never laughed at any of my hairbrained ideas - and by doing that, the hobby stuck and 28 years later, I am still doing hairbrained things and (thanks to the net) am asking silly questions on the newsgroups myself.

I thought about the question more. If he grounded the dish and attached 50+ feet of wire to the center element he might have a nice longwire antenna! Of course, the dish would be moot at that point. That's why the whole thing struck me as funny.

Frequently, so little that it may be ignored. At very high frequencies, it
can be significant.

Cross-posted to: sci.electronics.equipment,misc.industry.electronics.marketplace,rec.radio.amateur.antenna

The following antennas are for sale. All are fully tested and in very good to great cosmetic shape.

1) Sylvania ridged horn (no model number) 2-18GHz = $650.00
2) Polorad model CA-L 1-2.34Ghz =$300.00 2 each
3) Watkins Johnson model WJ8326-1A Quad ridge .75-4.8Ghz =$650.00
4) Empire device LP-105 12 inch loop antenna 150kHz-30Mhz =$100.00
5) Empire device LG-105 30 inch loop antenna 14khz-150khz =$200.00
6) Empire device AT-112/LPA112 Log Periodic w/ reflector 1-10GHz =$450.00
7) Electro-Metrics BDA-25 Broad Band dipole 20-200MHz =$275.00 1 each
8) Electro-Metrics ARL-25 Remote Switchable Loop 10kkhz-30MHz =$150.00 2 each
9) Tecom 802527-3 Directional Helical antenna 1775-2300Mhz =$150.00
10) Eaton 96002/Emco 3109 20-300MHz 2kw power rating =$600.00
11) HP 346B noise source up to 18Ghz type N connector =$500.00
12) Eaton Horn antenna 18-26Ghz w/waveguide =$400.00
13) Eaton Horn antenna 26-40Ghz w/waveguide =$600.00

Please e-mail for more complete specs and pictures. Buyer pays actual shipping charges. email address is wdizney@yahoo.com

Thanks for looking
Mike

I thought more about my analogy. I should have said "Can you tell me how to make my dog whistle into a tuba?" I think that would better illustrate the difference in the two wavelengths. A dog whistle at 25,000 hertz and a tuba at 100 hertz is a difference of 250 times. A 10 Mhz shortwave signal times 250 is 2.5 Ghz - YUP, microwave frequencies!!! As they say, hindsight is 20/20.

There are at least two different kinds of "loss" in this discussion...

What connectors such as the 259/239 series mostly have is reflection loss - due to failure of the connection to match the system impedance. Each connector pair inserts a very short section of lower impedance than 50 ohms (due to the oversize inner conductor) but there is no power dissipation in this kind of mismatch, so nothing burns up.

The reflection loss from a single 239/259 pair is probably trivial at 144MHz, but if you use too many of these connectors then problems build up along the line. Each connector reflection can either add or cancel with another one, depending on the electrical length of line between them - but Murphy is there to make sure they will add. The result can be a surprisingly high apparent SWR, from an antenna you believed was well matched. This can lead you into the next kind of loss...

Dissipative loss is the one that makes cables warm and can burn up connectors - but it *must* involve resistance somewhere.

Resistance inside the connector itself means either a bad contact (series resistance) or water (shunt resistance). This is unimportant for connectors that are in good condition and correctly assembled. 259/239 connectors can handle many kW up through 144MHz. Likewise N connectors are good for 1.5kW at 432MHz... but they do have to be perfect. If they aren't, you soon find out!

Transmission lines have dissipative losses of their own. Generally what makes coax get arm with high power is, in order of importance: skin effect resistance of the inner conductor (series resistance causing I^2*R dissipation), skin effect on the outer conductor, and least of all dielectric loss in the insulator (shunt resistance causing V^2/R dissipation). These losses are present even when the SWR is 1. An SWR of

1 means there are no periodic variations of voltage and current along the line, just a very gentle decrease along the line due to the losses. This is the least-bad situation.

Extra dissipative loss is caused in cables when the SWR is not 1. This is because there are current maxima every half-wave along the line where I^2*R losses are magnified, and voltage maxima where the V^2/R dissipation is magnified. There are various graphs and programs (and an Excel spreadsheet on the 'In Practice' web pages) to calculate these losses for typical cables.

So non-constant-impedance connectors such as the 259/239 generally don't *have* serious dissipative losses themselves, but they do cause minor reflections which in turn can *cause* dissipative losses in the line.

Source record: 146093

A friend of ours on 75 meters just took his B&W down and replaced it with a dipole because he was consistantly 10 dB or more down from everyone else. I realize anecdotal reports don't mean much, but now his signal is on par with the others. BTW (and I hate to admit this Cecil), the strongest signal in the group comes from a dipole at 90 feet fed with open wire and matched with a tuner.

It turns rf into heat. Most of the ones I've heard were more than one
S unit down from a coax fed dipole. I guess yours feels lucky...

> Those who want to get every miliwatt into the ether a cut and tuned

Hummm, not really...Mine are all full size.

The closer an antenna is to a
> match between the output impedance and the wavelength of the frequency
> and the space/time to install/cost to obtain.

That paragraph hurts my head...Can I pass on that one?

> Anything else is personal choice. I don't look down on you for yours,
> give me the same.

Well, I don't look down on yours either, but I'm not going to
misdescribe it either. It's an 200$ air cooled dummy load with wires
attached. Thats the plain truth about it. Maybe the wires radiate a
larger portion of the RF applied than the dummy load turns to heat,
maybe not, but it is what it is. There are plenty of antennas I've
used here that I don't like either. It doesn't bother me if I badmouth
them. It shouldn't bother you. I once ran a hustler vertical ground
mounted. It was a overpriced dummy load on a stick. I'm sure that bugs
the heck out of hustler when they read that, but I just don't care.
I'm a redneck. MK

I don't think you understand what the military wants or needs from an
antenna system. Military applications involve a lot of frequency
hopping with very short stays on a particular frequency often just
seconds. Rest assured that they don't assume gain they just run
what ever power they need. The military had been using TFDs since
at least the Second World War. We Hams sometimes suffer under
the delusion that they are smarter than non Hams when in reality
we just have a different hobby.

Hi Steve,

The one from Rhino International is on sale (at many of those gas
station/convenience store hybrids) at only $8.99.

Mine cost $19.99 last Summer...and that was in taxless NH.

73,
Chip N1IR

I'm totally unfamiliar with these things. Are these $10-20 ones
different in any way than the ones on ebay that sell for less than a
buck + a couple bucks shipping?

Gentlemen;

Why are some of you making fun of the question posed by the original writer? Remember that the only stupid question is the one not asked. The original writer wanted to know the answer to his question. Just because the rest of us know that this in a very impractical device to use as a HF antenna doesn't mean that he knew it to. Obviously he didn't now he knows not to ask question on the net.

Once again. Yes a dedicated dipole cut to frequency will out perform a
B&W. But a B&W will outperform a dipole off frequency.
Besides 10dbm is only 1 s-unit.

Mark

We agree. You are doing your thing, very well I hope, and I am doing my thing.
BTW I have said all along that nothing will beat a tuned dipole for a given band or sub band. But the B&W is intended to provide the user with a matched antenna on all frequencies. It is just not as efficient as a tuned dipole on any given frequency. To each his own.

Actually, you are comparing apples and oranges. The T2FD is used in field applications where portability is the most important consideration. A kilowatt amplifier is easier to move quickly than a big antenna array. Go to any fixed site, particularly overseas, and look at what the military (gov't) uses on the stationary end of the circuit. Huge LPAs which operate down to 3 MHz, inverted cones, funny spirals for NVIS, still a few Rhombics, 1000 ft. dia. CDAAs for DF and receiving, and so on. I'm watching some of the bigger fixed and rotating LPAs, hoping I can catch one when it is surplused. There's a big Grainger fixed LPA at the CG receive site in VA which always makes me drool when I pass it, and an AS-3195 (rotatable 3-30 MHz LPA) that's been off the tower for a couple of weeks in Texas which I'm curious about the disposition of.

Absolutely untrue, David. An "off frequency" dipole radiates just as
well as a resonant dipole. My 130 ft. dipole, which uses no antenna
tuner, is more efficient than the B&W on *all* HF bands.

5722. Re: $200 for a folded dipole?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-27 17:17:15 UTC
From: Patrick Croft <mai@iquest.net>
Message-ID: <3CA1FE9B.4D2AE34A@iquest.net>
Source record: 146110

B&W's patent on this is expired (era 2000). The patent was issued for
the purpose of providing the asignee (actually an employee B&W) some
protection while supplying the US military this item which they desired
for ALE operations. It was at the gov't request.

On Wed, 27 Mar 2002 08:30:01 +0000, "Ian White, G3SEK" <G3SEK@ifwtech.co.uk>
wrote:

[snip]

|The reflection loss from a single 239/259 pair is probably trivial at
|144MHz, but if you use too many of these connectors then problems build
|up along the line. Each connector reflection can either add or cancel
|with another one, depending on the electrical length of line between
|them - but Murphy is there to make sure they will add. The result can
|be a surprisingly high apparent SWR, from an antenna you believed was
|well matched. This can lead you into the next kind of loss...

To be sure. This is why in wideband systems there is much concern about keeping
individual device VSWRs low. Multiple mismatches, even little ones, can cause
significant VSWR ripple as the frequency is changed. The relative phase of the
mismatches changes with frequency allowing constructive and destructive
interaction.
|
|Dissipative loss is the one that makes cables warm and can burn up
|connectors - but it *must* involve resistance somewhere.
|
|Resistance inside the connector itself means either a bad contact
|(series resistance) or water (shunt resistance). This is unimportant for
|connectors that are in good condition and correctly assembled. 259/239
|connectors can handle many kW up through 144MHz. Likewise N connectors
|are good for 1.5kW at 432MHz... but they do have to be perfect. If they
|aren't, you soon find out!
|
|Transmission lines have dissipative losses of their own. Generally what
|makes coax get arm with high power is, in order of importance: skin
|effect resistance of the inner conductor (series resistance causing
|I^2*R dissipation), skin effect on the outer conductor, and least of all
|dielectric loss in the insulator (shunt resistance causing V^2/R
|dissipation). These losses are present even when the SWR is 1. An SWR of
|1 means there are no periodic variations of voltage and current along
|the line, just a very gentle decrease along the line due to the losses.
|This is the least-bad situation.
|
|Extra dissipative loss is caused in cables when the SWR is not 1. This
|is because there are current maxima every half-wave along the line where
|I^2*R losses are magnified, and voltage maxima where the V^2/R
|dissipation is magnified. There are various graphs and programs (and an
|Excel spreadsheet on the 'In Practice' web pages) to calculate these
|losses for typical cables.

|
|So non-constant-impedance connectors such as the 259/239 generally don't
|*have* serious dissipative losses themselves, but they do cause minor
|reflections which in turn can *cause* dissipative losses in the line.

My point is that old wives are constantly stating that UHF connectors have X db loss (insert your favorite number) when in fact they don't have a clue.

It is extremely difficult to measure said loss with any precision because there are no standards with which to even calibrate a measurement system in this connector series.

So let's pretend I'm still employed and someone walks into my lab and says, "I'd like to know the loss in this 'UHF' connector (the DUT)."

We'll make it "easy" and say that it is a female barrel connector. For my HP-8510C Vector Network Analyzer I have two sets of calibration standards: 3.5mm sexed connectors and 7mm sexless connectors. (There are type N standards, but at $5,000 a set for reference standards and cables, I opted not to buy them)

I pick the 7mm set and perform a full two-port, 12-term error corrected calibration. Now what the hell do I do? There aren't any 7mm to UHF adapters that I'm aware of so the best that I can do is install a pair of 7mm to type N adapters followed by a pair of type N to UHF adapters.

Now we've already agreed above that mismatch loss can mimic dissipative loss so we need to be able to characterize the mismatch loss. It's not enough to connect the two test cables together and "normalize" and then insert the DUT and say, "Eureka, 1 dB."

Back to the adapters. My basic error-corrected calibration will have an equivalent directivity of 60 dB or so with commensurate source match. Really good 7mm to N adapters might have 40 dB return loss (and close to zero dissipative insertion loss) so installing these has already degraded my directivity and source match to 40 dB. Still pretty good considering what comes next.

I add two N to UHF adapters. A ballpark guess is that these have 20 dB RL (1.22:1 VSWR). This reflection is so much greater than the 7mm to N adapters that it swamps their contribution. Result, my $200K analyzer with 60 dB directivity just became the equivalent of a $200 MFJ analyzer with 20 dB directivity.

But, there's more. The DUT is what is called a "non-insertable device." The input and output are the same sex. So, I can't even do the expedient thing of connecting the two test cables together directly and normalizing to 0 dB because I would need one male and one female test connector. With precision sexed connectors (3.5mm for instance) matched length adapters are used in this situation. It the DUT is female-female (our case), then a "through" connection using a male-female adapter is used to normalize the through calibration. But I don't know of any precision UHF male-to-female adapters to use for this operation.

So the best that can be done is to back up and perform a through calibration using one N female and one N male adapter and then installing the N to UHF adapters, which means that their mismatch and insertion losses are part of the measurement. Which part? Who knows? And that is the crux of the problem.

Now I would seem to be arguing with myself because earlier I stated that high loss in these connectors is an old wives' tale and now I'm saying it can't be measured accurately.

But I really can have it both ways. By inspection it can be inferred that real dissipative loss is low. These connectors have, after all, relatively big conductive surfaces and fairly minimal dielectric. Unless they're full of water or suffering the effects of having been full of water, the ohmic losses are inconsequential.

So what's the problem? Well, it is as stated by Ian in the last quoted paragraph above and in my remarks on VSWR ripple.

But pragmatically speaking, at 2 meters and below and extra connector in the system somewhere is probably immaterial.

WES goes WAYYYYY out in left field with a lengthy description of connector analysis - ignoring that
the ORIGINAL post was on the adviseability of series-connecting 3 separate pieces of RG-8 coax into
a single longer run - remember?

> OK, here's another question. How much loss is there in connecting
> two, maybe three sections of RG-8 for the 2-meter? In other words,
> maybe one length of 75 feet connected to 35 feet connected to 35 feet
> for a total length of 145 feet.

NOW, visualize the (assumed) *SIX* additional male PL type plugs, and *three* matching barrel
connectors - as well as the additional liability of degradation due to potential moisture intrusion
over relatively short time period, added to the fact that the coax being used is undoubtedly ALREADY
well into its lifespan from prior use - and THEN tell us all that this is INDEED a fully reasonable
and acceptable proposal for a new 144 mhz installation - as compared to spending the money for the
RIGHT full-length of better stuff...

Not for MY VHF installation it ain't!

Hi Wes, and all,

This seems to be a problem of the forest and the trees.

It would be presumed that the loss of "one connector" is immaterial in
that it must be connected to another connector. Rather, the problem
is the loss of the "connection."

That is relatively easy to measure through substitution (as long as
the substitution does not add significant error, a not unlikely event
here). Or: simply measure the power delivered through a cable, then
break it, connector the broken ends, connect them, measure the power
delivered through the connectored/connected cable. The difference is
surely the insertion loss.

So much for the forest. The trees present another angle to the
mismatch problem, and one more to the matter of failure. Any
connection that presents a mismatch must have its voltage and current
specification linearly derated by the value of the SWR (from any
source of mismatch for that matter). I would offer, it is the voltage
breakdown that will get you every time with the consequent ohmic
failure through a carbonized path and avalanche conditions following.
This is a dielectric issue at the connection.

Why would it perform any better off it's design freq? The resister is
still there sapping rf. If the normal dipole is fed with ladder line
and a tuner, or tuned ladder line sections with no tuner, I'd bet
either one would beat the B/W on nearly any freq. As far as 10 db,
thats hard to describe in S units as all the radios's vary, but in my
overall experience, 10 db is usually about 2 s units on the average
radio appx mid scale on the meter. This will also be about the same
increase seen going from a barefoot rig at 100w to one with an amp at
appx 800-1000w.

I bet thats more due to the height than the method of feeding. Coax
fed should do just as well, if not slightly better. He's kickin tail
cuz he's at 90 ft I bet. I bet his edge gets larger the farther out he
talks also, compared to the others. I've seen similar results from
guys around this state with the same appx antennas. "high dipoles
compared to lower dipoles or loops" . MK

5731. Re: Suggest coax for long run

I want to raise a caution about the use and interpretation of "reflection loss", which I've seen in a couple of recent postings.

If you have a fixed 50 ohm resistive source and a fixed 50 ohm resistive load, then insert between them a connector or other component that causes a reflection, the power in the 50 ohm load is reduced. The amount of this reduction is called "reflection loss" or "mismatch loss". Likewise, if the 50 ohm load impedance changes, the reduction in power it gets can be calculated from its reflection coefficient and attributed to "reflection loss" or "mismatch loss". It comes about simply because the source can't deliver as much power to any load that doesn't match its output impedance as it can to one that does. It's a valid and convenient concept that's widely used in laboratory environments.

But let's say you have an impedance matching device (e.g., antenna tuner) at the output of the source. You change the load impedance, or insert a reflective connector. This changes the impedance seen by the source. But by readjusting the impedance matching device, you can restore exactly the same amount of power to the load with exactly the same amount of power from the source as you had with no reflections. So where's the loss? The answer is, there isn't any. Reflections, by themselves, aren't a cause of loss (except for increasing the transmission line loss somewhat, usually much less than the "reflection loss" -- more below). "Reflection loss" refers to a reduction of power being dissipated in the load as a result of an impedance mismatch between the source and load. If this mismatch can be corrected anywhere in the system, the "loss" goes away. If the mismatch is corrected at the source, all the reflections are still present except the one at the very source, yet they no longer cause "reflection loss".

So be very careful not to misinterpret "reflection loss" and think that reflections are actually a source of this amount of loss. Only when the source has a fixed, resistive output impedance (like a laboratory signal generator) and no matching device is present is the concept of "reflection loss" valid.

When a transmission line operates at an SWR above 1, its loss increases. The amount of this added loss depends on the loss of the line when matched, and in general is negligible for reasonably low SWR or when the matched line loss is reasonably low. This increased loss is usually much less than the "reflection loss", and shouldn't be confused with it.

.....dummy load on a stick.

. MK

Mark,

That's like the arguments I keep having with a certain organization I belong to that uses a ra-
ther extensive HF system. They like to promote the B&W FD to its members, but I wasn't
having any of that. They also like those hamstick thingies (YECH!!) on organizational vehicles or high-priced couplers and whips. ALL of which equate to the "dummy-load-on-a-stick" you mentioned. I am afraid I am one of those "every 'nth of RF I can pump out guys. Oddly enough, it was that emergency services organization that taught me that to start
with back when I was a kid. One of their arguments is they are afraid that, since *some* of their members are merely appliance ops who only use radio to facilitate their other duties, they might not be able to "operate" antennas or radios that require tuning, etc. OK, I can
understand that, but what good is it if your emergency message doesn't get thru because the
antenna system is so user friendly, it doesn't WORK?

For us hams, it isn't so critical to get every last ounce of RF out, and the choices of antennas
are, indeed, our own to make. My habit of trying to have as efficient a system I can is just
the way I was elmered in my early days in radio.

Apparently ALE (automatic link establishment) brings such tremendous advantages in establishing reliable HF communications that it would be worth losing perhaps 6dB or so in the dummy dipole. ALE doesn't play well with antenna tuners.

This friend of mine has a Motorola Startac, flip phone. The batter is on the flip-up part so he put the booster behind the battery. When in use, the booster is actually up next to the top of the antenna. He was skeptical at first but upon traveling his daily route through a dead zone he became a believer. No more dead zone. Furthermore, it would never work in the basement of our building, now he gets 2 bars even with the antenna fully collapsed. Go figure that!

Roy makes good points, of which I am aware and should (almost did) have addressed earlier. The laboratory measurements that I described earlier are of course done with matched terminations.

When I closed by saying: "But pragmatically speaking, at 2 meters and below and extra connector in the system somewhere is probably immaterial", I had in mine the fact that in normal ham operation, the system is usually 'tuned' (dare I suggest "conjugately matched"). There will be no "mismatch" or "reflection" loss.

In the case of multiple mismatches, and giving the benefit of the doubt to Ian that Murphy will always prevail and the mismatches will add worst-case, then the addition loss in the line due to the higher operating SWR must be looked at in each section of transmission line separately.

For example (Using AC6LA's "XLZIZL" spreadsheet): 100 feet of RG-213 at 144 MHz has a little under 2.6 dB attenuation in the matched condition. If a 100' line is terminated at the antenna end with a 1.2 VSWR, at the input end the VSWR will be ~1.11 and the total line attenuation will be about 2.62 dB.

If we cut this line in half and install a connector pair let's see what happens. I contend, and therefore assume, that the dissipative loss in the pair will be no more than 0.1 dB and that a well-constructed connector, properly assembled will have 20 dB RL (1.2:1). The RL is likely to be overly optimistic but who can measure it, so I go forward...

The load end line is still operating with VSWR = 1.2 but is half as long. The attenuation is therefore: 1.31 dB and the input VSWR is ~1.15.

This then is the termination for the second 50' plus connector. Assuming once again a 1.2 VSWR for the connector, the worst case VSWR (Murphy doncha know) is 2.35:1. This mismatch causes the attenuation in the second 50' of line to be ~1.65 with an input VSWR of ~1.85:1.

Thus an approximation for the total line attenuation is 1.31 + 0.1 + 1.65 ~ 3.06 dB or about 0.4 dB more than without the added connector.

Now in this case, all of the respondents are correct (sorta). Bill says, "sometimes the losses in the connectors is (are) as great or greater than the loss in the coax". Well, the 0.1 dB (assumed) loss in the connector increased the system loss by 0.4 dB, so he looks like he knows what he's talking about even if the mechanism isn't really dissipative loss in the connector.

Ian is right on, if Murphy has his way, about mismatches increasing dissipative loss, but as Roy states, reflection loss is only a laboratory problem.

Richard correctly worries about increased loss in the connector itself from increased stress but incorrectly, IMHO, believes that substitution measurements can ascertain the loss contribution of the connector. Not in this case. In a matched system, the measured difference between the two cases would be considerably different from 0.1 dB.

Gary says, once he gets his math straight, "Not in my system", with which I agree.

I believe as stated above, it doesn't make much of a difference. In an EME system, yes, but then you would be using a line with over 2.5 dB loss in the first place, connector or no connector.

Throw in some more connectors then you should be RSSing the effects unless Murphy is really in a foul mood.

Hello to all. The Cape Cod ARES is loking to experiment with some beams for long range 2 meter VHF. We are looking for any designs of 3,4, and 5 element antennas for testing. We wanted to actually build the antennas as part of the project. We have several peices of 1" aluminum tubing for booms and 1/4" aluminum rods for the elements. If anyone has any designs or can convert using these conductor sizes(Have not played with antenna software much), we would appreciate it. We are experimenting to see which beams will work best for us. We will likely need several designs since some will have to be rugged, while otthers may need to be expedient to assemble and disassemble. If anyone has designs, spacing and length parameters, or suggestions, We would be grateful. These designs will go into provinding emergency communications in time of disaster for the community here. Thanks in advance. Nice bunch of folks on this group.

Source record: 146030

The following is an extract from a reply to a private enquiry about failure of HF multiband antenna tuners around 30 MHz. It seems a pity just to consign it to the junk heap.

==========

There's not very much written about impedance matching/transforming networks simply because there's very little to be said about them. They are the most simple of circuits. At most there are only 3 components and only two of them need be variable. There is usually a chapter on the subject in books on network theory, communication enginering, etc. If you can't understand its only because you are unfamiliar with the language which many academics delight in unnecessarily overcomplicating.

My several impedance matching and similar programs are adapted from the simple formulae all sorted out in the Victorian era.

Incidentally the rec.amateur.radio.antenna newsgroup is the best to use. I have a regular argument on there myself. There's a knowledgeable set of contributers. As usual they are mixed up with ill-informed do-gooders and old wives. It is difficult to distinguish between the sheep and goats. And they are all inclined to overcomplicate matters in order to display their great knowledge. It's only human nature.

The best book I have ever come across is a chapter on "Impedance transformation" in W.L.Everitt's "Communication Engineering", McGraw-Hill Book, Inc., 1937. I've had it for 54 years. It's never been improved upon. Although ancient I would expect this classic to be available in technical and university libraries. But I must stress the basics are very simple once they have been grasped. There is no real need to go as deeply into the subject as Everitt might take you. Its only a bit of algebra.

Terman, as is his wont, just gives you a set of numbers and graphs he has plagiarised from somebody else, without providing much idea about what's really going on. His graphs are not of much use unless you already know what you are doing.

The basic calculating formulae for T, Pi and L networks are very simple. Only a pocket calculator is needed. I used to find a slide rule quite adequate.

As I have said before, the problems at 30 MHz are due to the physically large components needed to handle several 100 watts which inevitably introduce stray capacitance and stray inductive reactances. The networks in reality are more complicated than simple T's and Pi's. But any complicated network can be treated as several in tandem with an impedance match at each of its junctions.

Across every component is a stray capacitance. In series with every component is stray inductive reactance. From each component is a capacitance to ground. But at 30 MHz this can be controlled. It means only that component settings will be somewhat more or less than the values predicted by assuming a simple L, T or Pi circuit.

THE TROUBLE ARISES WHEN THE COMPONENT VALUES NEEDED ARE OUTSIDE THE RANGE OF THE ACTUAL VARIABLE COMPONENTS USED. It is a matter of practical experience in choosing physical size and values of L and C components, in conjunction with theoretical computed values which neglect the strays.

Come back to square one. You will appreciate that to provide a match between two impedances YOU WILL GET ABSOLUTELY NOWHERE UNTIL THE VALUES, R+jX, OF THE TWO IMPEDANCES ARE APPROXIMATELY KNOWN. Otherwise you are floundering about in the dark.

IF YOU WANT TO KNOW THE INPUT IMPEDANCE OF THE TRANSMISSION LINE TO THE ANTENNA THERE IS NO ALTERNATIVE BUT TO MEASURE IT. Any SWR measurements at the transmitter end will tell you next to nothing. Otherwise the best you can do is copy what somebody else has already done. A photgraph of the inside of the tuner box is all that's needed.

There's a matching network. The input impedance on the transmitter side of the box is hopefully 50 ohms + j0. On the antenna side there is another impedance which can vary over a wide range. It will be a complex impedance. Before you can do anything at all it is essential to know what the antenna or line input impedance actually is. The best way of finding out is to MEASURE IT. THEN DO THE CALCULATIONS.

But I repeat again - it will probably be quicker to wind a few turns of wire on a coil, obtain one or two 50pF or 75pF variable capacitors, and see what happens with one eye on the SWR meter. That's what the professionals do. Following that, if they have the time to spare, they write a learned treatise, with imaginary numbers in it, about how clever they are. ;o)

Programs T_TUNER and L_TUNER are relevant. Pi_TUNER to follow.

Ooops. Speaking of Murphy... I totally misread the reflectometer
slide rule. The composite VSWR is more like 1.35 (more accurately
1.38) which makes much of the following bogus. But I don't have time
at the moment to correct the numbers but I can say the effect is even
less than stated.

5744. help rebuilding a DK3

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-28 04:37:43 UTC
From: Peter Shintani <shintani@cts.com>
Message-ID: <3CA29E16.E721C0B@cts.com>
Source record: 146032

hi:
I recently received an old Dk3 screwdriver antenna.
In the base of the antenna, I found two relays, one marked
40m, and the other marked 75m. Attached to the relay contacts
were two trimmer caps, a pair for each relay. I don't know the
builder of the antenna but after tracing out the schematic, it
looks as if the common lead for the relay power is the same as the
antenna
connection ! I assume that the caps are in a shunt connection to ground
from
the base of the antenna. More capacitance for the lower band ?
Did the DK3 use a common lead for the antenna input and the common
power
return lead for the relays ? My guess is that the relays common return
lead is separate from the antenna lead.

Any help or schematics are appreciated.

Also what length of whip is recommended for best efficiency on 20m ?
and also for 40m ?

Caps will work to twist the impedance to 50 ohms from 15+jX. A
coil will also work to twist the impedance to 50 ohms from 15-jX.
The beauty of a coil is that the shunt reactance increases with
frequency so you can leave it installed permanently.

Well, it is an acceptable alternative if you give it some context. Many of the classic references were written when MW AM was the extent of broadcast. It is reasonable to divide MW propagation into two major parts, skywave and groundwave. The groundwave can be further divided into the surface wave and the space wave, but these two are so intermingled at MW that it makes some sense to treat them together. At VHF+, a clear break between the space wave and the mostly insignificant surface wave starts to make more sense (and the skywave becomes a rare anomaly).

As can moving a piece of sticky-back foil, whether it cost $29.99 for
2", or $2.99 for a 50ft roll.

I can actually change the reception of my TV antenna quite a bit by
moving the roll of aluminum foil tape around on the table.

I know if I tune up my dipole with a transmatch at 14 MHz and go to 21
MHz, it ain't worth hoot. If I retune it will certainly work better, but
I haven't seen a Genie included with a high-buck wire antenna to
mitigate this phenomena.
Maybe it depends on the rig/tuner? :-)

No, an "old wife" is what you call a person who makes a point you're not able to refute. It's much simpler than trying to convince by means of logic, and it gives the aura of great knowledge without imposing the requirement of even knowing very much about the topic in question. Watch when the term appears on this newsgroup, and you'll see that this is its function.

I'm not surprised. I did some tests at an antenna test range in Detroit some years ago, and found that moving the front car seat forward and back made a noticeable difference in the positions of nulls in the pattern from an antenna positioned where a typical driver's cell phone would be.

Hi All

I would like to put up a tx/rx 160 meter antenna, but very restricted on space. Garden only 66 feet long, 12 feet wide with some trees at the bottom about 30 feet high. Any suggestions or designs please on a 160 meter aerial to fit this space. Only needs to take 100 watts.

Here's a couple of good VHF antenna design choices: DL6WU and K1FO. A google search returned the following:

Yagi-Uda design program by DL6WU at http://xe1mex.gq.nu/antenas/yagi.html
or
ANTFO v2.0 YAGI ANTENNA DESIGN at
http://users.tpg.com.au/mmtodd/html/hamradio2.html

I've used them both with very good results on 2, 220, 432, 900 and 1296. I believe Steve, K1FO used the "WU" as a base and optimized it for his designs. The ARRL Handbook has some of the K1FO designs, too. If those standards fit the tubing you have (or even if you have to start fresh), use them. They have been tested and WILL WORK.

I'm sure wiser heads will have better ideas, but I'm cheap so I'd just run a wire from as high in a tree as I could to a stake at the other end of the garden; plus bury some wires beneath it for a counterpoise. I'd connect them via a large coil homebrewed from single-conductor houshold wire at the stake then experiment with where (on the coil) to tap in the feedline to get the best SWR at the xmtr. Don't fall out of the tree ... :o)

Do not try this at home !

we could not get tickets to the world series so we just put a few of these sticky antenna boosters inside our baseball caps.

Wow, now I get all the local, cable and satellite channels directly into my head !

Bad thing was our late friend Roy, he put ten of these things under his cap and his brain exploded.

Yes, that's right. I use 6 turns (one inch) of 1.5" diameter coil stock.
The inductive reactance is minimum on 75m and maximum on 10m. So it
is most effective on 75m, where it needs to be, and essentially out
of the circuit on 10m because of its relatively high reactance.

My antenna system *is* matched on all HF ham frequencies. Although the
dipole length is non-resonant on most HF ham frequencies, the ladder-line
is used as a series section transformer to achieve a 50 ohm SWR of less
than 2:1. All of the transmitter power (minus losses) is delivered to
the antenna.

A 50 ohm antenna accepts all the power (minus losses) from 50 ohm coax
but there is no law of physics that says a 100-j100 ohm antenna can't
accept all the power (minus losses) generated by the transmitter. All
that is required is a Z0-match in the antenna system. A Z0-match can
often be achieved without using an antenna tuner, i.e. using the feedline
as the matching circuit.

The Selectenna is a tuned circuit consisting of a coil and capacitor.
The field of the coil couples to the loop antenna in the AM radio.

I'm assuming the cellphone antenna is resonant on the cellphone band
and the field of the resonant antenna couples to the cellphone antenna.

I think the original poster was looking for VHF yagis in the 3-5 element
size, whereas the K1FO, DL6WU and DJ9BV designs for 2m are primarily
'long-yagis'.

Check out WA5VJB's designs at

http://www.clarc.org/Articles/uhf.htm

These antennas did well on the test range, considering their
relative simplicity...

I certainly agree. My one line answer (as with almost all one-line
answers) was far too incomplete to begin to cover the subject.

I assumed a dipole cut to a frequency on a single band, fed by coax
from a rig with no tuner or other matching other than the output of the
transmitter. If a dipole, it will have a pretty narrow range of
frequencies at which it will accept most of the RF presented to the
coaxial feedline input. Match this coax input with a tuner (or match the
antenna at its feedpoint) and you can normally work all across the
single band involved. Without matching, working other bands will not
likely be possible with this single dipole, nor will excursions in
frequency of more than a few Khz.
Your antenna system matches the the feedline and/or antenna on all the
bands you have arranged for it to match.

Roy Lewallen wrote:
"Richard Harrison has a Terman reference that speaks of the "ground wave" having two parts, a "surface wave" and a "space wave".

True, and I tried to copy Terman exactly. The two part ground wave follows directly from Fig.1 in Terman`s section on "Propagation of Radio Waves". This section is general as it includes very low-frequency (below 100 KHz) and ultra-high frequency (above 30 MHz).

Fig.1 is a diagram of two paths, a direct ray between two antennas and a ray which is reflected by the earth. The reflected path also links the two antennas. The difference in path lengths means the two rays can be in-step, out-of step, or anywhere in-between. It depends on the path difference as a fraction of a wavelength. The summation of these two waves is Terman`s ground wave. It is not a sky wave because it does not include reflection from the ionosphere. It is not a space wave because it does include reflection from the earth.

Terman said: "The ground wave is that portion of the radio wave that is affected by the presence of the ground and would account for all the energy reaching the receiver if it were not for ionospheric waves (sky waves) and tropospheric waves.

The ground wave can be conviently divided into two components, a surface wave and a space wave."

Terman`s explanation is logical and stands the test of time.

Reg`s defamation of Terman does not hold up. Except for our own discoveries, what we know was discovered by others and is repetition. Terman scrupulously foot notes and provides bibliography. W.L. Everitt is in Terman`s author index six times. It would also be unfair to say Terman contributed nothing original.

Different professors have different styles and attract different followers who are more receptive to one style or another.

I found unanswered questions in various studies and if Terman covered it, the subject was clarified for me when I read Terman. If Reg prefers Everitt, that`s his prerogative.

Terman agrees with Gary Coffman that "The space wave is any signal taking the direct line of sight path---", but when it comes to reflections of the space wave, reflections from the ground may make the reflected ray part of the ground wave received by an antenna.

When the direct ray is influenced only by the atmosphere, the wave is a space wave, though it too may encounter tropospheric reflections.

When the space wave is reflected by the ionosphere, reflection from the reflecting boundary make it a sky wave.

Others may define things differently, and my take on Terman may be flawed. It wouldn`t be the first time. But, I`ve never found a flaw of substance in Terman`s books.

Best regards, Richard Harrison, KB5WZI

5768. Re: Cell phone antenna booster

Newsgroup: rec.radio.amateur.antenna

Message-ID: <3CA3566C.6CC60259@dialpoint.net>
Source record: 146056

AM has nothing to do with it. The basic antenna coupling will work on AM, FM , or any other RF type of transmission. The main key is the internal antenna is very small interms of wavelenght. Almost any conductor larger will couple to the AM broadcast antenna. You can streach a wire out about 25 feet long or more and wrap 5 ot 10 turns around the AM radio and it will improve the reception in many cases. For the cell phone frequencies you can get a similar effect if you put up a good antenna outside your house , run some good feedline to an antenna inside the house and then put the cell phone antenna close to the inside antenna.

5773. Question

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-28 19:45:39 UTC
From: Mark Tetrault <tetrault@mv.mv.com>
Message-ID: <v5s6auki1dr4jr7pf9hc73biq4olmeecm8@4ax.com>
Source record: 146061

OK here's the scenario:
I have a G5RV flat top configuration suspended between two trees. It's 50' at one end and 40' at the other. It runs NE to SW.

I recently installed a W9INN 160-80-40 dipole as an inverted V. Bill cut it to be 35' at the center and 8' off the ground on the ends, and it's installed that way oriented the same way. The SWR based on my freq. wish is spot on.

Here's the question:
Why does the G5RV, which is a massive compromise on 80 and 40m, receiving and transmitting better than the W9INN? When I copy other stations on 40 & 80m, no matter where or who, I get a 2 S unit gain in signal strength both receive perceived by my ears and eyes on my meter, and signal reports indicate a louder stronger signal from my rig with the G5RV too. I would have thought that the W9INN not being that much lower in height than the G5RV would out perform the G5RV given it's designed for the frequencies mentioned above.

On 160 of course the W9INN blows the G5RV away.

Ideas??

Mark

The G5RV is *NOT* a massive compromise on 80m and 40m. It has the typical dipole radiation pattern and the 27 ft 300 ohm section actually does a pretty good job of matching the antenna to the 50 ohm coax. The SWR on the 50 ohm coax for both 75m and 40m is relatively low. The G5RV is a darned good antenna on 75m, 40m, 20m, and 12m.

Are your two antennas oriented the same direction? I don't know anything about the W9INN antenna but it might be developing a cloverleaf radiation pattern on 40m. I would suggest that you determine the radiation patterns for a better comparison. The free EZNEC demo will probably model those two antennas pretty well. Try: http://www.eznec.com

Makes sense to me. The surface wave is more useful on the low frequencies. On the higher frequencies, the space wave is more prevalent. Also the surface wave is attenuated at a much higher rate, the higher in frequency you go. I have no data on it, but my guess is the space wave is fairly constant in comparison through the spectrum not counting local ground and tropo effects. I think almost all VHF/UHF "ground wave" propogation is almost all space wave unless you are real close to the transmitter. On 160m, you could have a fairly even mix at certain distances I would think with the surface wave being stronger fairly close in. Seems to me at certain distances on 160m, you could have cases where the surface wave mixes with the space wave, and then you get another mix of skywave. And indeed at certain times of the early evenings 160m can get kind of weird sometimes. Lots of fading, shifting around, etc. MK

5779. Magnetic loop??

Newsgroup: rec.radio.amateur.antenna

I hate to say so, but anyone who has a G5RV at a height less than 500 feet above the middle of the Atlantic ocean and imagines he has a cloverleaf or any other peculiar pretty pattern is deluding himself. Or herself.

For practical purposes, taking one band with another, and one backyard with another, a G5RV is omnidirectional, in both horizonatal and vertical planes, regardless of idealised computer programs.

Remove the coax and the G5RV with its openwire feedline performs just the same as any other random length dipole. Keep the coax and it is marginally a dB or two worse at the higher frequencies.

And Louis Varney, that rare, modest, English gentleman, whose British G5RV callsign will be be long remembered, would agree.

5781. Can I build a 2m/440mhz 5/8 mobil antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-29 00:28:33 UTC

Message-ID: <3CA3B531.B027B191@sprynet.com>
Source record: 145969

I built a dual band 1/4 wave 2m mobile antenna which
resonates fine on 440 mhz (third harmonic). My question is
can I build a 5/8 wave 2m mobile antenna that will also
resonate on 440 as a 5/8 on 440? Anyone have a source of
plans? Also I noticed that the commercial dual band 1/4 wave
length antennas have a coil (trap?) up past the 440 length
(about 5"). Why is this necessary if it resonates naturally
on both 146mhz and the 3rd multiple on 440 mhz?
Thanks,
Jeff WB9FOL

Reg, when I lived in AZ, I put up a N/S G5RV. I couldn't seem to
work any DX. That's when I bought ELNEC and observed the radiation
patterns. Most of my 20m RF energy was hitting the oceans instead
of land masses. I turned the G5RV N20W and the DX started pouring
in. In fact, the reason that Mr. Varney chose 1.5WL on 20m for
the original G5RV antenna was because of the cloverleaf pattern.

Hi Andy,

I suggest to build a top loaded vertical, inverted L :

30 feet up, horizontal wire about 90 feet slung between one of the trees and
a distant 30 feet pole, bendet to earth or elsewere at the end if space not
sufficient. Resonce should be around 1700kc
Feed at the bottom via shortening capacitor to get 50 ohms impedance to feed
with standard coax.
Use as many radials as possible.

This antenna will be especially for long haul dx

For domestic distance build doublet as long as possible with
centre feed via openwire feeder

Hi Chris,

I have made a few over the last couple of years. Here are my opinions...

PROS:

Great manmade noise rejection
Great QRM rejection
Good performance for its size
Relatively cheap to make (see CONS!)
Great weekend project

CONS:

Extremely narrow bandwidth
Constant tuning when you QSY
Tuning caps hard to find - I picked up a vacuum variable very cheap (until
it smashed!!)
Caps must be very high quality to withstand the several KV's of voltage
across them, even at 100W output

I built mine out of 3/4" copper tubing rolled into a 3' circle. Cap was a
5-475 pf @ 5KV. The loop would tune anywhere between 4.8 - 24 MHZ with
absolute 1:1 SWR. Worked stations up & down the east coast on 40m while it
was still in my basement.

Good luck

Max ve3tmt@rac.ca

There is lots of information on Magnetic Loops (aka
Small Loops). Try a search on any good engine such
as google or yahoo and use AA5TB as your search term.
He has an excellent site with lots of good links.

==========
Hi,

A magloop is much the most efficient of the small antennas where real estate is at a premium. It can also be said, it is much the least inefficient.

Small means small in comparison with a wavelength. A perimeter of 1/20th of a wavelength is very usesable. But like ALL antennas the higher above lossy ground the better. Think in terms of a height greater than 1/3 or 1/2 of its diameter. A whole diameter is lovely.

It is more of an indoors workshop than an outside job. For most convenient construction make a square loop from 1" or 1.5" copper plumbing pipe. For 160 metres you need a 6000 KV, 900pF, 30-amp, very-slow-motion variable capacitor. That's expensive. But capacitance decreases very fast with frequency. A motor-driven vacuum capacitor is very nice if you can afford it.

The most efficient way of coupling the loop to the transmitter is a much smaller, self-supporting loop made from bare copper inside the main loop and insulated from it. Nothing could be more simple.

On 160m and 80m it is 2 and 1.5 S-units down on a full-size dipole at a height of 100 feet. But that's not surprising. It makes best use of a 30 feet by 30 feet back yard. At 14 MHz it is almost as good as a dipole. At 30 MHz you have room to put up a full-size 1/2-wave dipole anyway.

You can't make a beam out of one of them. One vertical loop has the same radiation pattern as a horizontal dipole only better. You could use two of them to make the same sort of pattern as a dipole with a reflector. But you would then need at least 1/4 or perhaps 1/2-wavelength of garden space. Don't think about it !

For main loop and coupling loop dimensions, capacitor pF, working voltage for power input, download program MAGLOOP4 from website below. Takes only a few seconds. Then get a blow-torch and solder.

5790. experimental antenna design

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-29 05:26:11 UTC
From: Aaron Rogerson <arogerso@bigpond.net.au>
Message-ID: <TVSo8.23650$EE4.77394@news-server.bigpond.net.au>
Source record: 145978

Opinions on this antenna design.....
Length of insulated copper wire with a length an even multiple of the waveform. Sections of brass rod slipped over the insulated wire... 1/2 wavelength long with a hole drilled into the end, and wire threaded through the hole would around and then wound around a small section of the wire which has had a small section of the insulation removed. Have maybe 20 of these "elements" rods connected to the insulated wire along its length at spaces of one wavelength each. The whole thing going lengthways across the roof from one end to the other similar to a simple dipole arrangement. Each element connected at sections to the wire is facing vertically, eg sitting on top of the insulated wire... with some assistance from some electrical tape.....

Any thoughts on this design?

5791. Cigar Antennas for 2400

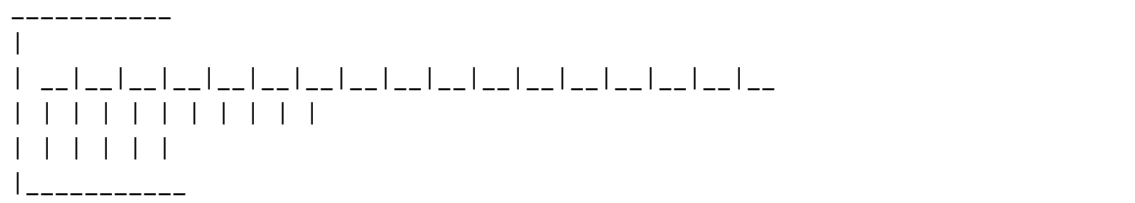
Hi Group
Any one out there have any pointers on where to find info on construction and theory behind the "cigar antenna" Invented by a Frenchman named Simon. The usual configuration for 2400 is a rod with 1 inch diameter washers and spacers stacked on it for a couple of feet.



This the rough outline, since I don't know the proper name internet searches don't turn up much. Looks like quite a bit of gain with easy non critical construction. I would particularly like to know what the critical dimensions are.

5793. Re: Can I build a 2m/440mhz 5/8 mobil antenna?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-29 06:42:46 UTC
From: Roger Leone <arleone@inreach.com>
Message-ID: <M0Uo8.1081$jW7.99572862@news.inreach.com>
Source record: 145980

Jeff:

A 1/4 wave on 144 MHz is 3/4 wave on 440. The SWR is usually acceptable on the 3rd harmonic, although that is partly due to the increased feeder losses on 440. But SWR is not the whole story. A 3/4 wave radiator on 440 has radiation lobes that send some of your signal at high angles, not toward the horizon where you probably want it. This is usually not so severe to make the antenna unusable, and may be considered a reasonable compromise for the dual band coverage.

A 5/8 wave antenna on 144 MHz is 15/8 waves on 440. If you do the simple math you will see that on 440 you will have almost a 2 wavelength antenna, which is becoming what we call a "long wire" on the HF bands. As you probably know, a long wire radiates with multiple lobes, the largest of which are toward the ends of the wire. In other words, most of your signal will be radiated up toward the sky.

The reason for the coil in commercial dual band antennas is to phase the antenna currents so you actually end up with two colinear elements which both radiate at low angles, reinforcing each other and providing gain. Without the phasing coil you get multiple undesirable lobes.

Also keep in mind that 5/8 wave is NOT a resonant length. There are several ways to compensate for the reactance at the base of a 5/8 wave radiator, the easiest being to add a small inductance in series which makes the antenna electrically equivalent to a 3/4 wave. (3/4 wave is resonant, as you have already discovered).

Given that the gain advantage of a 5/8 wave antenna over a 1/4 wave antenna is probably not noticeable except under the most difficult conditions, and even then may or may not make a difference, my suggestion is to stick with the 1/4 wave antenna. It is simple and works OK.

Having started my life in amateur radio on 160m, making an antenna shorter tends to be against my principles!

I used a base-loaded CB whip for 10m FM (with a modified CB set plus retuned CB 40W 'burner'). I didn't cut the whip or take turns off the coil. As the CB antenna was inductive above its 'correct' frequency, I simply inserted a compression trimmer capacitor in series with the feed point (between the coax inner and the bottom of the coil), and adjusted it for minimum SWR. I then measured the value of the cap (220p?). I then replaced this with a fixed disc ceramic (500V) of the same value. OK on 40W (and I worked Jamaica and several US repeaters).

Cheers,
Ian.

Hi Chris,

These are interesting antennas and if your search the net for Small transmitting loops you'll find more than you ever wanted to know.

I've built several here and for their size they do a great Job. They are very HI Q antennas which is good and bad, Good because it adds a messure of selectivity on RX , but bad in that they must be retuned every few HZ of frequency movement.

I would Recomend making the Loop out of 5/8 inch or 3/4 inch copper tubing it's easy to work with and not that expensive. I used Aluminum conduit also for one of my loops and found the copper to be better here.

The Cap is the important thing, It must be able to handle Kilovolts of volage.. Butter fly type is better from a resistance point of veiw. and when working with only a few ohms of radiation resistance everywhere you can make a very non resistive connection counts. Also I've tried both methods of feeding the Loops. Gama and Link coupled with small coupling loop. Use the Coupling loop and forget the gama match schemes.

Have fun they are great little Antennas for their size and work quite well low to the earth if mounted in the vertical plan.. mine were only 4 ft above ground.. try that with your dipole..

Sounds something like a colinear dipole, except they use coax instead
of a single wire. Typically, though, you usually see only two or four
sections.

There was a program called Yagi Optimizer that would be ideal for
what you are doing. It compensated form boom and element diameters,
and also the types of element to boom mounts used, and element tapers.
It would automatically design the best possible yagi based on the parameters
entered by the user regarding boom length, number of elements, SWR
BW, etc.; and it was an extremely easy and informative program to use.
I don't know if it is still being marketed (saw a demo many years ago),
but I think Brian Beasley (sp?) was the author.

Chris, Not all magnetic antennas are small. On 75 M I used a 20 Degree, Multiple U (MU) which is a Magnetic Radiator-a Low profile Paried Vertical. The design is extremely simple, only wire ! It requires some real estate, but you don't get anything for nothing. See The ARRL Antenna Compendium , Volume 2. The article was written by Russell Prack, K5RP. This antenna design is extremely efficient, due to very low ground losses. I used mine for over a year and exprerienced more or less an omni-directional pattern. I worked JA which was at a null azimuth. This is a DX not LOCAL antenna.

I can't help with a name but, a decade and more back, a Ham was selling
a kit TV rcvr. The printed circuit board soldered to a coffee can to
make a resonant chamber and used a homebrew antenna just like you
describe aimed at a dish sold for kids to sled on. Maybe that'll jog
someones memory and get you a name. AFAIK it's just a special Yagi.

5804. L-network Revealed

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-29 16:15:39 UTC
From: avatar <avatar@frii.com>
Message-ID: <3ca493ae$0$69924$7586b60c@news.frii.com>
Source record: 145992

L-Network Revealed

While a T or a Pi network provides the greatest matching versatility when all three reactances are adjustable, the L network in many cases is a better choice. Why?

Based on most of the material I have read related to L networks, one is lead to believe that it can only match a purely resistive source to a purely resistive load. In the real world the load usually has reactance as well. To compensate for the reactance the article suggests putting a reactance of opposite sign and equal value in series with the load. This approach has made the L network into a T. The fact is that this suggestion may be totally unnecessary! If the reactance in the load is within the tuning range of the L network, that reactance with the L network forms a T network that can provide a matched condition. An advantage of using an L network, whenever possible, is the lower Q and lower probable losses. For those cases where the L network cannot match a given load, then an additional series reactance will provide a greater matching range.

The above can be proven mathematically and in practice. The only two references I have found that provide the mathematics are

1.Communication Engineering by Everitt, Pub. McGraw-Hill. (This is the same reference recommended by Reg - G4FGQ)

2. Matching Network Design by Tony Dorbuck - K1FM, QST March 1979.

Either of the above references provide the formulas that prove my statements. Further, if one knows the R+jX of the load and substitutes the jX into the T network as the series output reactance, the L part of the network can be calculated. It appears that G4FGQ has included this feature in his L network program. I confirmed the resulting values that the program produced by doing the same problem long hand.

In addition to doing the theoretical exercises, I have done some real world experiments related to this article. Those activities support the statements made herein.

Reg is to be commended for unselfishly providing many useful computer programs related to antennas for free. You can download these programs at www.btinternet.com/~g4fgq.regp/

BTW: For G4FGQ. If you are willing to give me an email address, I would like to correspond with you.

Dave,
I'm curious -- did you have troubles with the gamma
match?
I have a loop that is just waiting for better weather so I
can put
it out. It is still snowing in the area here!!! I have it
constructed
with a loop match at the moment, but plan to try the gamma
as well.
(I was really lucky and picked up an MFJ 1786 for $100 --
only had
to repair the controller unit).

I also plan to try two kinds of couling loop -- one straight
wire,
the other a sheilded loop made of coax. I just can't help
myself --
have to try everything!!!

Source record: 145995

Hi Dale

Thanks for the reply. What I was really looking for is the proper name for the director structure. So I could conduct a proper search. I have seen these things around but never paid much attention to them. I want to use them for point to point networking on the 2.4 ISM band. I have some 18 inch instrumentation type dishes (f/d 0.5)with log-periodic feeds and was thinking about replacing the feed with something that would increase gain and give a cleaner pattern. Then decided it might be eaiser to build the whole ant from scratch. So I am looking around.

Trick is I don't have much instrumentation for this frequency so design has to be cookbook and work the first time without tweaking. The cigar looked like a very simple design to fabricate but I need a little theory to know what is critical. Like what is optimum disk spacing, diameter, is diameter of the center rod critical, etc.

73 Eric

At 08:08 AM 3/29/02 -0500, you wrote:

Hi Eric,
These antennas were popular for MDS TV where polarity could easily be changed by
using a 2nd set of U bolt holes. The disc parasites work of course respond to
any polarity- so only the waveguide cavity had to be turned. Gain is somewhat
lower than loop yagis- which are superior for amateur use.
If you are still interested, look at microwave dish feeds for 2306 MHz- this is
the driven element- designed for very deep dishes (i.e. small F/D).

I have never found a load that cannot be matched to 50 ohms by an
appropriate "L" network.

An L should match anything it's true, but sometimes the components would get unwieldy values. Then an extra reactance can be of help. In transistor PA's for instance, a T network could be easier to work with then an L because of the strange values that your components would get.

Source record: 146000

Hi Jan,
well, first I would see where the SWR was best. If it was exactly right, I would stop ;-) Otherwise...
Then I would tune the traps so that the "inner"dipole was on the desired higher frequency.
After that, I would prune the end wires so that the whole dipole was on the desired lower frequency.

Example: for a 40/80 dipole, first trim the traps so that SWR is lowest on 7.05 MHz (for Belgium).
Then trim the wire ends so that SWR is lowest on 3.6 MHz, or wherever you like (it will be a bit narrow on 80 so you will have to make a choice there).

For more bands, work from inside out as above, always doing the wire ends last.

Note, I do not know _how_ you can tune the traps. Remove/add windings, solder small capacitors, perhaps there is a trimmer capacitor or a moveable slug in the coil. Designs differ.

Good luck!

To match up the impedances between the coax and the twinlead, I'd use a 6:1
balun between them. This is of course assuming the use of 50 ohm coax.

==========

If anyone should wish to correspond with me privately following one of my newsgroup postings it is necessary only to select "Reply to Sender" instead of "Reply to Group".

I can be also be contacted directly from several places in my website just by by clicking on "Reply to Reg" or something similar.

And if by some remote chance none of the aforementioned should work, my e-mail address is g4fgq.regp@btinternet.com. I have only that one address.

But I am astounded at the number of private e-mails I receive. It has been entirely unexpected. I cannot suggest a short explanation. It is far too much of a job to respond to all enquiries. I do do the best I can. Nevertheless I cannot but be selective. Just let it be said it is a gratifying experience.

Most enquiries come from North America. But that's understandable because most of the world's radio amateur population resides in that fortunate region of this over-populated Earth. And of course we have a common language.

The fact is I don't know what to do about it. So I take the easy way out by doing nothing. Except doing what I like best - just writing another program.

If anyone should consider I'm perhaps a little too frivolous, you are probably right.

Regards, Reg, G4FGQ

We don't know what the SWR on the coax will be. If it is acceptable to you,
then the answer is yes. It is good engineering practice to place a balun
or choke at the coax to twinlead junction.

> balun between them.

The impedance at the coax to twinlead junction will be Z0 squared divided
by the antenna feedpoint impedance. That will certainly be nowhere near
300 ohms. A 6:1 balun is a very bad idea. Assuming Z0 = 300 ohms and
the feedpoint of the antenna is 5000 ohms, the impedance at the coax to
twinlead junction will be about 18 ohms. A 6:1 balun will try to take
that impedance down to three ohms. That's a very bad idea. 18 ohms will
give an SWR of about 3:1 on the coax which is acceptable. Three ohms
will give a 50 ohm SWR of 16.7:1 which is terrible. Why spend big bucks
for a 6:1 balun that makes the antenna system worse?

A better approach would be to use "450" ohm ladder-line instead of
the 300 ohm stuff. The impedance seen by the coax will be closer to
50 ohms. The original Zepps used open-wire transmission line.

Thats been pretty much the case for me too. Only on a few very low impedance loads on the low bands have I ever had any trouble, and that was just because the inductor/cap were not quite the correct values. I use an L network for my mobile impedance matching most of the time. Add another cap to the other side of the inductor to make a "universal"?? match, and you don't need to reverse the tuner connections to go from lo to hi Z. Just a cheap 39.95 MFJ random wire tuner will tune 90% of any loads you will ever see although you may need to reverse the connections at times. MK

Message-ID: <1017481119.920283@aknx2.orcon.net.nz>
Source record: 146010

I am trying to receive a station towards the north about 30 Km away transmitting at 100w. I can receive the station in stereo but with hiss, so far I haven't been able to improve it much further than that.

My current setup:
An external 5 element FM antenna (The shop said that was the largest they had) mounted vertically which is pointed directly at the station towards the north and is feed into 20m long RG-6 coax run directly connected to the back of my stereo.

I did try placing the antenna in a slanted and in a horizontal position, but the reception was poor.
When adding an old preamp I had lying around , all station are are wiped off, supposedly because the amp is overloading due to the presence of 50Kw stations transmitting about 6Km away towards the NW .

Is their anything else I could do in attempt to improve the reception of this station, or am I out of luck? :-/

5823. Loop and ladder line??

Bill,
Always use enough ladder line to reach from the radio
to the antenna. If the radio and tuner aren't 'happy'
with whatever that length is, add a few extra feet and try
again. Repeat till radio and tuner are 'happy', then quit.
'Doc

For making an 5/8 wavelength ground plane antenna with 3, 4, or more radials at an obtuse angle of @ 135 degrees to the vertical element how long should they radials be in wavelength relative to the resonant frequency of the antenna? Should all radials for vertical ground plane antennas be 1/4 wavelength long regardless of the length (wavelength) of the vertical element (1/4 or 1/2 or 5/8 wavelengths)?

5827. Re: 5/8 Vertical Ground Plane

Newsgroup: rec.radio.amateur.antenna

From: Crazy George <munschNO@attglobal.net.SPAM>
Message-ID: <3ca5cbcd_3@news1.prserv.net>
Source record: 145872

Yes. Approximately.

The radials need to present a low impedance at the common point. If you make them a half wave long, almost no current flows in them and they are ineffective. Some very old experiments showed that radials of about 1.05 or 1.1 times a quarter wavelength are the most effective at producing a signal at 0 degrees elevation angle. The radiator length principally affects the feedpoint impedance and thus what kind of matching circuit is necessary to transfer maximum power from the feedline with minimum reflections. The drooping radials are an attempt to lower the feedpoint impedance of quarter wave radiator, and it is not necessary to droop them for longer elements which require matching anyway.

Message-ID: <3ca5cbcf_3@news1.prserv.net>
Source record: 145873

You have several options, none simple. First contact the station and determine if indeed they are transmitting a significant vertical component. If they are not, then your received signal is likely corrupted with a lot of multipath, and will never be crystal clear on stereo, or see below for another possibility.

There are much longer antennas made. A quad stack of wide spaced 10 element beams is not unknown among rabid distance (DX) chasers. I would start by doing a search on the Internet for some of the FM DX clubs/organizations, as a pointer to antenna sources. A 'tuned to channel' preamp , which are probably no longer made, would help. Also, you may already have overload problems in your receiver from the local high power stations, and that is why turning the antenna vertical helps, as it reduces the relatively pure local signals more than the scattered distant one. In that case, you need a fairly sharp (read expensive) front end filter to accomplish what you seek, or a better FM receiver. Again, I defer to some of the presently active DXers for specifics.

If you have access to old magazines in a library or somewhere, there was an article in Radio and TV News back in the 50s or 60s which showed how to stack 2 antennas horizontally (side by side) to develop a deep null to the side whose direction is determined by the spacing. This would allow 'nulling' the local while still providing good forward gain.

Or, you could dig deep, buy the station a 10 KW amplifier, and file for a license modification for them. One of these is about as expensive as the other.

Yes.

But not simply.

You need to rip into the radios and bring out the transmitters and receivers
separately. Either that or build a antenna relay matrix to keep the
transmitters from frying the receiver front ends of the others.

Short answer , no. There may be special ways to do it but no simple way
if you are transmitting and recieving.

Kinda like comparing apples and oranges. The Hexbeam--and most other multiband antennas--are fixed-tuned at some point in each of the bands covered. On the other hand, each element of the F-M is continuously adjustable over the antenna's frequency range--allowing it to be programmed in an infinite number of ways.

I can see no reason that you couldn't make a loop into a beam by adding the proper director and/or reflector loops. Tune them loke a yagi, 5% higher in frequency for a reflector, 5% lower in frequency for a director. Space them like you would a yagi, and go. (you wouldn't feed either, of course). Your problems would seem to be mostly mechanical, and the fact that you would probably have to also retune the parasitic elements when changing frequency very far.

I have a pair of phased PAR loops, the top one at 29 ft on the side of a tower. My 100 watt operations on the MAGIC 6M band are sporadic. In the past 3 yrs from NM , I have confirmed 41 States and over 120 grids including DX to Vanuatu. If the YL would agree on another antenna I would augment the loops with a beam to focus the RF.

I have used multiple radios on 1 antenna for recieving and transmitting. the thing on transmitting is never have the radios on the same bands that you are transmitting on and also have a real good switch between them to change from one radio to another. i have had lots of fun doing this and checking out different radios..
On recieving you don't have to have a switch to go between radios. I have a 19" rack that has 3 recivers in it and all are on the same antenna and work great..

just my input..

> watts power most of the time on 75 meters.
>
> Thanks, Bill

Hi Bill,

Ladder line is very forgiving as to length as Doc has already mentioned if you find a frequency that you can not match add a few feet.

I have a 500 ft. loop up about 35 ft here it's a very nice general usage antenna.. If you running 500 watts I would go with 45O ohm 300 is not quite enough.. I like the 14 ga stuff also lasts longer .. and this will be a long term antenna once you give it a chance..

Results here @ 2w or less output level.. 96 qso in 15 days 27 states and 22 countries not bad for one antenna.

Check my site "Amateur Radio Station KC9CS" at http://home1.gte.net/res0958z/index.htm for an overview of my install, then try the following sites: http://users.erols.com/n3rr/lightningprotection/index.htm and excellent page with pictures, then go to http://www.anarc.org/naswa/badx/antennas/grounding.html for a very good article on grounding for radio installs, then hop over to the Polyphaser site and sort through the technical information there. It is at http://www.polyphaser.com/ppc_technical.asp . Some other very good pages can be found at http://www.geocities.com/SiliconValley/2775/gndsys.html "Grounding Systems for Amateur radio stations, and don't miss "Lightning Protection at K9WK" which you can find at http://www.k9wk.com/litenin.html . Finally, an entire site devoted to grounding is at http://www.hard-core-dx.com/nordicdx/antenna/ground/ . That should keep you busy for a moment or two. Hope this helps...

73,
Bill

I agree that more antenna gain and the best polarity choice will help. I
also agree that more height may help. You might also try using RG-11 coax
with high quality connectors to minimize the loss.

Amateur Radio Newsline™ Report 1285 - March 29 2002

Amateur Radio Newsline report number 1285 with a release date of Friday, March 29th, 2002 to follow in 5-4-3-2-1.

The following is a Q-S-T. Russia orbits a new but temporary ham radio satellite and the ARRL says its time to re farm the Novice bands. What is refarming? Find out on Amateur Radio Newsline report number 1285 coming your way right now.

(Billboard Cart Here)

**

HAM RADIO IN SPACE: RS-21 IN OBIT

Yet another ham radio satellite is now in space. This one is the Russian Radio Sport 21. Roy Neal, K6DUE, has the details:

--

Meet the latest ham radio satellite: RS-21. The newest ham radio satellite.

The satellite's formal name is the Russian-Australian Scientific and Educational Microsatellite Kolibri-2000. To most hams however, it is simply Radio Sport 21.

According to the AMSAT News Service, the new ham-sat was remotely launched on March 20th from a Russian Progress M-1-7 launcher that had brought supplies to the International Space Station. That launch took place after the Progress ship had un-docked from the I-S-S.

Alex Zaitzev, RW3DZ, the director of the Microsat Office of the Russian Space Research Institute, describes RS-21 as a non-government, non-commercial project, built with cooperation from students in Russia and Australia. It is currently in a circular orbit just over 200 miles above the Earth and on the air. Downlink frequencies are listed as 145.825 and 435.335 MHz.

The birds uses both CW and FSK for its telemetry transmissions, but it wont last very long. Zaitzev says that RS-21 was designed with a limited lifespan and that it will fall back into the atmosphere during the late winter or spring months. Till then though, RW3DZ, says that the satellite will send down data and digitally recorded voice messages.

For the Amateur Radio Newsline, Roy Neal, K6DUE.

--

Meantime, the L.A. Daily News reports that the current crew on board the International Space Station will be spending an extra month in orbit. Russian Cosmonaut Commander Yuri Onufrienko, RK3DUO along with American Astronauts Carl Walz, KC5TIE and Dan Bursch, KD5PNU will spend the time correcting problems with the Canadian built robotic arm used for ongoing I-S-S construction. This will mean the crew will be on board for a total of 189 days. This will be a new record for the US crew members on board the International Space Station. (AMSAT-NA)

**

HAM RADIO IN SPACE: HIGH SCHOOL CHEMISTRY EXPERIMENT TO THE ISS

A small science experiment at two Bloomington, Indiana High Schools is now headed for the International Space Station. A ham radio operator is helping to make it happen. Amateur News Weekly's Jack Parker, W8ISH, has the details from the home of Indiana University.

--

Eleven honors chemistry students from Bloomington North and Bloomington South High Schools have collaborated with NASA to prepare a protein crystal growth experiment. The protein, frozen since November, is now ready to be transported to the International Space Station.

Bloomington North advanced chemistry teacher Neil Rapp, WB9VPG will join the students as they travel to the Kennedy Space Center for the April 4th launch of the Atlantis space shuttle. Once the experiment is aboard the International Space Station, it will thaw and allow the crystals to grow. After the crystals are formed, they will be transported back to earth and studied by NASA, and eventually returned to the Bloomington High schools.

According to Neil Rapp, the formation of protein crystals is an important step in the development of drugs designed to cure various diseases.

Reporting for Amateur News Weekly, this is Jack Parker W8ISH.

--

All eleven chemistry students will be on hand for the launch of Atlantis. Each will receive a plaque and shirts designed to commemorate the launch of their experiment into space. (WB9VPG)

**

ARRL TO FCC: TIME TO RE-EVALUATE THE NOVICE BANDS

The ARRL has asked the FCC to eliminate the 80, 40 and 15-meter Novice and Technician Plus Morse code subbands. It also wants the FCC to reuse that spectrum, in part, to expand the radiotelephone allocations on 80 and 40 meters. Amateur Radio Newsline's Bruce Tennant, K6PZW has the details:

--

According to the ARRL Letter, a Petition for Rule Making filed March 22nd, the League requests that the FCC revise its Amateur Service rules in accordance

with the modified Novice band refarming scheme the ARRL Board of Directors okayed in January. The Petition has not yet been put on public notice for comment.

Refarming is a government-ese term coined a few years back. Its a way of saying that spectrum assigned to a given radio service will be reassigned for other uses within that service. In this case, reassigning spectrum now primerally dedicated to Novice C-W operation to various other modes.

If the FCC approves the plan, current Novice and Technician Plus licensees would be permitted to operate on the 80, 40, 15 and 10-meter General-class Morse code allocations at up to 200 watts output.

The ARRL's petition also asks the FCC to permit amateurs to use spread spectrum on the 222 to 225 MHz band. It also requests an expand the pool of special event call signs beyond the 1 by 1 format to include identifiers for US territories and possessions that do not provide for mailing addresses. And it asks the FCC to clarify its rules to indicate that modulated CW is permitted for repeater station identification.

For the Amateur Radio Newsline, I’m I’m Bruce Tennant, K6PZW.

--

In its petition, the ARRL cited substantial advancements in the use of “digital techniques” in the HF bands such as PSK31 to bolster its assertion that a refarming plan is needed. The ARRL says that the Novice High Frequency sub-bands are underutilized and Amateur Radio cannot wait any longer on this issue. A copy of the ARRL's complete Petition for Rulemaking is available on the ARRL Web at www.arrl.org. (ARRL)

Break 1

From the United States of America, We are the Amateur Radio Newsline, heard on bulletin stations around the world including the Montgomery County Amateur Radio Club repeater serving Washington D C.

(5 sec pause here)

**

A NEWSLINE FOLLOW-UP: A POLITICALLY DISORGANIZED 11 METER CLASS D SERVICE

A few weeks ago we reported that the FCC has refused to hear an appeal by an Illinois C-B operator convicted of Disorderly Conduct for interfering with a neighbors home entertainment electronics. In the days since that report first aired, it caused quite a stir on several Internet discussion groups. Everyone wants to know how a service that once boasted 3 out of every 5 Americans with radios in their cars could wind up where the local sheriff or policeman could take an operator off the air.

After a bit of research, the answer seemed pretty clear. In one word: Politics. Here is Amateur Radio Newsline’s South East Bureau Chief David

Black, KB4KCH, with part 1 of a multi part look at the strange political side of 11 meter C-B.

--

When it comes to having political representation, most communication groups are in good shape. Hams have the American Radio Relay League looking after their political well being. Broadcasters have the powerful National Association of Broadcasters. Cellular telephone companies have the CTIA. Even the General Mobile Radio Service, which shares frequencies with the Family Radio Service, has representation amid the Personal Radio Steering Group. So, what form of communications lacks representation? That would be 11 meter, Class D Citizens Band radio. What does CB have? This:

--
Sound from 11 meter CB
--

Give CB a listen, and you hear lots of people using a service without any structure or formalized representation. Some might even call it anarchy.

--
More sound from 11 meters
--

Ironically, CB's lack of political power--as well as its inability to defend against bureaucratic attack--is not due to shortage of people using the airwaves. Many believe that next to cellular telephones, the second largest selling piece of 2-way radio equipment in the 20th century has been the CB radio.

During the gas crisis in the 1970s, many cars sported some sort of 11 meter whip and a cheap CB radio under the dash. Low cost 11 meter radios by the millions were manufactured, imported and sold. The industry had hobby magazines and several newspaper style newsletters devoted to CB radio.

CB operators outnumbered hams by at least 20 to one. And they outnumber GMRS users by 1000 to one.

But CB was not able to defend itself from outside pressures either back then or today. Why? Part of the reason goes back to CB’ers themselves in the 1970s and early 1980s. Most of them were not really interested in the service. It was just a utility. A way to help learn where to find the cheapest gasoline or avoid speed traps.

The CB radio service lacked any real monetary commitment. Without that, there was no political commitment. And when fuel prices began to ease, many but not all 11 meter operators pulled their radios out of their cars--and put them in the attic.

Then there were the few others, the die hard CB hobbyists. They treated CB channels 1 through 40 as a sort of ham radio-like hobby. Some operated illegally, but would take the chance just to make a DX contact. But they never organized. Why?

Different CB groups formed over the years. Many called themselves political messiahs of 11 meters. But many turned out to be bogus.

During the late 1970's and early 1980's, C-B radio scam artists were busy, trying to separate the 11 meter radio operator from his hard earned cash. As group after group appeared and then vanished, it became apparent to most using C-B that trusting anyone was too expensive. Now, more than 25 years later, trust in any C-B political organization seems little more than a remote possibility.

And what about the legal C-B operators? Those dedicated to public service? That part of the story, next week.

For the Amateur Radio Newsline, I'm David Black, KB4KCH.

--

Next week David tells us about the only successful C-B organization and the reason that it survived when the rest went away. (ARNewsline(tm))

**

SHORTWAVE: ARNEWSLINE VISITS AN SWL-FEST

From C-B to shortwave listening. Ham radio operators are not the only radio hobbyists who hold conventions. So do Short Wave Listeners and one of the most successful gatherings is Winterfest. Amateur Radio Newsline’s Steve Coletti took his tape recorder and visited this years gathering. He has this report:

--
AUDIO ONLY - NO TEXT. Download MP3 audio at www.arnewsline.org by clicking on the newscast number.
--

It may not be the size of the Dayton Hamvention or Huntsville Hamfest, but to Short Wave Listeners, Winterfest is truly the best. (ARNewsline(tm))

**

RADIO GROUPS: NEW MURS USERS GROUP FORMING IN CYBERSPACE

We have covered C-B and short wave listening. How about MURS -- the newly created Multi-Use-Radio Service. Well, according to an Internet posting, an organization called The MURS OPEN Group has begun work to form an Internet-based MURS User's Group. This group will be a non-profit corporation whose main goal will be to encourage the growth of Multi-Use Radio Service. If you are interested in learning more, you can visit the group in cyberspace at: http://groups.yahoo.com/group/MURS-OPEN/ (MURS Open Group)

**

CONVENTIONS: WELCOME TO HAM RADIO AT NAB

If you are planning a trip to the upcoming National Association of Broadcasters convention, be advised that the hams of Las Vegas are expecting you. Bill Croghan, WB0KSW, says that the Las Vegas Radio Amateur Club repeaters are up,

active and hard linked.

Bill Croghan is the Chief Engineer of Lotus Broadcasting in Las Vegas. He says that on two meters try 146.94, minus 600 kHz offset with a 100 Hz access tone. This machine is now located on the Hilton hotel immediately above the Convention center, but on the opposite tower. From this site it should be useable from deep inside the Convention center and easily from anywhere on the Las Vegas strip.

If you would rather use a U-H-F machine try 448.500, minus MHz offset also with a 100 Hz access tone. This system is hard linked to the 2 meter machine but located on the old Tropicana hotel site as in years past. With the two systems linked any ham attending N-A-B with either a 2 meter or 70 centimeter radio can have fun and stay in touch. The convention takes place April 8th through the 11th at the Las Vegas Convention Center in Las Vegas, Nevada. (BEAN)

**

CONVENTIONS: WELCOME TO THE NAB HAM RADIO RECEPTION

Also, this years N-A-B Ham Radio Reception will take place Wednesday Evening, April 10th at 6 PM following the close of the exhibit hall. Location is the Hilton Convention Center in Ballroom B. The gathering is being co-sponsored by C-Q Magazine and Kenwood Communications. C-Q Publisher Dick Ross, K2MGA and Editor Rich Moseson, W2VU, along with Kenwood’s Paul Middelton, K4NUH, will be there as your host.

Amateur Radio Newsline will also be loitering around the convention and the Ham Radio Reception. We will be represented by Producer Bill Pasternak WA6ITF and by Todd Hitzeroth, N6ZXJ, who serves on the Young Ham of the Year Award committee. (CQ, ARNewsline(tm))

**

BREAK 2

This is ham radio news for todays radio amateur. From the United States of America, We are the Amateur Radio Newsline with links to the world from our only official website at www.arnewsline.org.

**

EMERGING TECHNOLOGY: KERMIT AND THE V-CHIP

Sesame Street’s Kermit the Frog has a new part-time job. According to news reports the little green guy will be put to work boosting the awareness of the television V-Chip.

The V-Chip is a mandatory internal accessory built into any T-V set larger than thirteen inches diagnal picture. The chip reads a digital code that contains a program's rating and can be programmed to block out television shows parents deem inappropriate for their kids.

Now the Hallmark Channel in conjunction with The Jim Henson Company, has donated the image of Kermit to the Federal Communications Commission for use in

an upcoming promotional campaign to bring attention to the availability of the V-Chip. A new brochure to be distributed to the public by the FCC, the Hallmark Channel and other interest groups, will feature Kermit sporting a "V" with his fingers and urging parents to monitor the programming their children watch. (Published news reports)

**

INTERNATIONAL - CANADA: VE7BFK IS NEW ARDF COORDINATOR

Gordon D. Young, VE7BFK has been appointed as the Radio Amateurs of Canada National A-R-D-F Coordinator. Young first became interested in A-R-D-F when the Friendship Amateur Radio Society hosted the 3rd Friendship Radio Games in Victoria British Columbia back in 1993. He has since attended A-R-D-F events in Russia, Japan and the United States. He replaces Perry Creighton, VA7PC who has held that appointment for several years. (RAC)

**

INTERNATIONAL - ISRAEL: 500TH NEWSLETTER ON THE AIR

From Israel comes word that Mark Stern, 4Z4KX, recently celebrated the 500th edition of his ‘Newsletter on the Air’ for that nations Russian-speaking ham community. Stern, the former UP2OE, has been performing this service for the last 11 years every Saturday morning on 7.080 MHz.

Stern also seeks donations of used gear that he donates to newly arrived new-immigrant hams. As a result of his efforts many have gotten on the air in Israel in only a short time after their arrival in that nation.

And if all that were not enough for one ham, Stern is also the Israeli Award Manager and issues the awards and trophies for the Holyland and Israeli VHF-UHF Contests. (Hagal International)

**

DX

In D-X, hams are usually out looking for D-Xpeditions. Heres a twist. A future D-Xpedition is looking for you. Jeramy Boot, G4NJH, explains:

--

Have you always wanted to take part in a major D-Xpedition, but never known how to get on an expedition team? Now could be your chance. Ken Holdom, ZL4HU, the leader of 'The Kermadec DX Association's' planned operation from the Chatham Islands - ZL7 - later this year, is looking for experienced SSB and CW operators to accompany the group. "As this will be a 24-hour-per-day operation, we are looking for operators who feel they have the willingness and ability to operate during both day time and night time," Ken says. For further information please contact the Kermadec DX Association, PO Box 7, Clyde, Central Otago, New Zealand or e-mail to zl2hu@clear.net.nz.

--

Again, that e-mail address to apply is zl2hu@clear.net.nz (RSGB)

A D-Xpedition to San Felix became active on March 16th as X-R-Zero C. It was active for 14 days on all bands and modes. If you made contact, QSL via John Kennon, N7CQQ, P. O. Box 31553, Laughlin, Nevada 89028.

Lastly, N6DE and K6EP will be active from St. Croix through April 2nd. During the CQ World Wide S-S-B Contest, they will use the callsign WP2Z. QSL WP2Z contacts via KU9C, and non-contest QSO’s to each operator's home callsign address. (Various DX sources)

**

THAT FINAL ITEM: AN APRIL 1ST CB D-XPEDITION TO THE ISLE DU CONEY

Earlier in this week's newscast we reported that 11 meter C-B has no political clout. What it does have is a bunch of people who just want to have fun. Now, a group of them is planning what they call a People's Radio D-Xpedition from an exotic island location. Roving reporter Pierre Pullinmyleg is here with the details:

--
AUDIO ONLY - NO TEXT. Download MP3 audio at www.arnewsline.org
--

Hopefully, Pierre will be back a year from now to pull your leg once again. (The April Fools Day File)

The L network has trouble when the two impedances
are nearly the same value. For example, an L
network cannot transform a 50 ohm load impedance
to a 50 ohm input impedance. There are small areas
on the Smith chart that lead to very strange
values. The CLC T-network does not have this problem.

Correction. I should have said 50 ohm load
"resistance" and 50 ohm input "resistance".

5853. FA: Mosley Pro-67 and more in Southern California

The link to this auction is below, you may have to cut and paste it in pieces as it's long. Mosley Pro 67 (10-40M) 7 element yagi PLUS KLM 11 element VHF yagi, PLUS 3 sections of roof mounted tower a couple of coax runs, and the guys... located in SoCal. Needs to be removed by purchaser. The rotor in this assembly is not included in the auction. More details in auction listing. I am open to reasonable offers to end the auction early, so if this is what you've been looking for...a big gun beam (98 pounds worth) plus extras...drop me a line. Paul NS6V

For a start, review the PolyPhaser web site. They, of course, have products to sell, but they also have a good lightning protection book available. It used to be free, but I think they charge for it now. Remember that there are various levels of station grounds, depending on such variables as to whether you want to leave antennas connected all the time as in a remote location, or want to disconnect them during thunderstorms. Also, if you need a counterpoise for an unbalanced antenna system, then there are many more and different considerations. For that, start looking at antenna handbooks.

You can get a ballpark idea of the optimum length of ladder-line by modeling
the antenna. Do you have an antenna modeling program or any friends with
antenna modeling programs?

Or go the extra mile, like I did, and feed at the current
maximum points, i.e. the low impedance points.

Why wouldn't a series 0.1 ohm inductive reactance (stray) and a
1 meg ohm parallel capacitive reactance (stray) do it? :-)

Which gives a total of eight different kinds of L-network. The trick is to know which is the one you need, especially if you probably don't know the value of the impedance you want to match. There is always a choice of two, but some other configurations will be totally incapable of matching impedances in the range you need. Reg's program helps you choose.

On the other hand, the CLC T-network will match a wider range of impedances than any single L-network configuration. This makes the T a good basis for a marketable antenna tuner, but it doesn't make it the best network for any given job. The T-network always operates at a higher loaded Q than an L-network doing the same job, and therefore the T-network has higher losses - much higher if the T-network is adjusted incorrectly.

Perhaps the best of both worlds is the CLC tuner with a fully variable L and also a shorting switch across each capacitor. The switches convert the T into either a step-down L-network (short C1, adjust C2 and L) or a step-up (short C2, adjust C1 and L) so you can use the more efficient L-network for those impedances that it's capable of matching. For the others, you still have the T-network.

Message-ID: <a85bhd$3tg$1@paris.btinternet.com>
Source record: 145899

"The best station ground system I can install" will make you bankrupt, a bottomless pit, a massive black hole, which will swallow up dollars. You really must consider very seriously your family finances. Put the futures of your wife and children, possibly your elderly parents, before the well-being of your bank manager and his/her staff who are very likely in comfortable circumstances.

Try to analyse what you already have and compare it with what you can reasonably afford and with what will provide an acceptable performance. You will immediately be confronted with how to attach numerical values to what you already have - the resistivity (or conductivity) of the soil in your back yard. Typical soils vary between 25 and 1000 ohm-metres, mean value about 150 ohms. Low values apply to fertile damp soils. High values apply to dry rocky soils with some vegetation. Just take a guess.

Acceptable performance of a ground electrode system is best measured in ohms. This is the RF resistance of the connection from the transmitter to the "ground system". It is a loss resistance. A low loss resistance is better than a high resistance until it becomes an insulator. Reactance of a ground reactance is of no cosequence since it can be tuned out simultaneously with the antenna reactance. How can the performance of a ground system with a resistance of Rground ohms be assessed ?

Ground systems are used with antennas. So there's no better way than to standard overall performance on other than a standard antenna - a 1/4-wave vertical. Primary interest lies in radiating efficiency of the system as a whole. The base feedpoint radiation resistance of a 1/4-wave vertical is Rrad = 37 ohms.

Radiating efficiency, therefore, is very simply, Rrad / (Rad + Rground) times 100 percent.

So what sort of efficiency can be considered as acceptable ? Look at the question in terms of received signal strength of a radio transmitter. If the strength of a radio signal varies within plus or minus 1/6 of an S-unit then for practical purposes such small variations are undetectable. 1/6th of an S-unit is 1 dB. A loss of 1 dB corresponds to a loss in radiated power down to 79 percent of previously.

And so an acceptable ground system loss resistance for a 1/4-wave vertical is 0..27*Rrad = 10 ohms.

The most efficient ground system is formed from a set of shallow buried wires radiating from a single point. (A single ground rod or even a group of closed-spaced ground rods make a very poor radio ground.) To crudely estimate the bare minimum number and length of radial wires, in average

soil, needed to provide a satisfactory loss resistance of 10 ohms for a quarterwave vertical at 1.9 MHz, use program EARTHRES.

It turns that 6 radial wires, about 27 feet long, of 10 gauge wire, at a depth of 10 inches, in an average damp sort of ground, will have a loss resistance about 10 ohms. This will be satisfactory for a 1/4-wave or higher verticals. For shorter heights more radials may be prefered. But be prepared to double number of radials before an improvement can be secured. The important aspect is that a ground system can be installed for a modest expenditure in labour and money.

When anyone mentions the magic number of 120 radials, each 1/2-wave in length, just put plugs in your ears.

The cheapest thing would be to switch to mono. That gains about 3dB.

>it does include reflection from the earth.

I disagree with that characterization. Both direct rays and rays reflected off of terrestrial objects are space waves. The receiver must be in the line of sight to either the transmitter or the object reflecting the signal from the transmitter. The primary property of the space wave is that it behaves as a straight line propagation method. Specular reflections don't alter that characterization.

The surface wave is different. It is a guided wave that follows the contours of the air/ground interface. It can reach receivers which are not in line of sight with the transmitter, nor in line of sight for reflections off of terrestrial objects which are line of sight to the transmitter. For example, the receiver could be behind a hill from the transmitter, or beyond the radio horizon for the transmitter, yet still be able to receive the signal.

This guided wave behavior is most prominent at low to medium frequencies. It is likely that 90% of the receivers picking up daytime Standard Broadcast signals are not line of sight to the transmitter. They work by capturing the surface wave. The surface wave is primarily excited by vertically polarized signals, this is why vertical polarization is universally used for Standard Broadcast station antennas.

By the time VHF is reached, the surface wave is for all practical purposes non-existent. Reception is via space wave, either direct, reflected, knife edge refracted, or via troposcatter. (I'm considering ducting, E-skip, etc as anomalities, not part of the routine day to day mechanisms defining the coverage area.)

That's why high sites are much more important at VHF and above than at MW and below. A higher site increases the radius to the radio horizon. That's not particularly important at Standard Broadcast frequencies, but it becomes critical for FM and TV broadcast which have to depend on the space wave for coverage.

Note that it is universal practice to use horizontally polarized (or circularly polarized) transmitting antennas for TV and FM broadcast. That's because there is no benefit to exciting a surface wave, which is primarily dissipative at these frequencies.

MW at night, and HF during all or part of the day, are primarily skywave for most of the area over which they can be received. A surface wave component still exists, but it provides a much smaller fraction of the total coverage area than the skywave. (And that fraction decreases with increasing frequency.)

Note that the skywave will have random polarization, due to the effects of Faraday rotation in the ionosphere, so antenna polarity is of less concern for skywave than for groundwave coverage. Use of circular polarization can help avoid deep fades, but at the cost of a 3 dB forward gain penalty.

Gary

I have obtained an interesting Antenna for which I am looking for some
Technical Information.
It is called a Cliff-Dweller and was Mfd by New-Tronics Corp probably in
1960-1970 era.
It is basically a rotatable dipole with a motor drive in the centre of the
dipole that moves the elements in & out until resonance or Low VSWR is
obtained. I have the two end coil assy & control box, but am looking to
resurect this Antenna by fabricating the centre/motordrive section, but need
Technical Info so I can try and ascertain just how it operated.
Any assistance would be appreciated.

What percentage of a wavelength is your antenna? Is it for transmitting
as well as receiving?

I have a rotatable dipole and all I have to do is vary the length of
the ladder-line at the transmitter. That's a lot easier than varying
the length of the elements at the antenna.

10 dBm is 10 milliwatts. (dBm is a measure of power referenced to
one milliwatt)

Now 10 dB is about 5 S units on many Japanese transceivers.
It is 2 S units on others. But it would be one sick receiver if it were
only 1 S unit.

Well, the best of all worlds is to go out and cut the antenna to frequency instead of trying to force an untuned antenna to accept power with a resultant pattern that you probably don't know and can't replicate.

5874. Re: Installing a good station ground system

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-31 02:37:56 UTC
From: Mike Coslo <mcoslo@adelphia.net>
Message-ID: <3CA67696.D8D686AD@adelphia.net>
Source record: 145912

I made a ground for my station that works pretty well, and was fun to make as well. I picked up some half inch copper pipe and made two six foot sections.

Next, sweat on a connection to one side of each pipe to accept a garden hose.

plan on placing the pipes at some distance apart so you can connsct the six foot sections with angles or "T's".

Attach a hose to the desired pipes, and place the pipe over the position you want, and turn 'er on. The water coming out the end of the pipe will act as a drill, and the pipe will work it's way down into the ground. Stop when you get maybe 6 inches above the ground.

Remove the garden hose attachment. Sweat a horizontal pipe between the two vertical pipes.

Sweat the appropriate pipes to bring the ground into your shack.

Note that you can add more vertical pipes if you like. Also of course if you are sitting right on top of bedrock this won't work. But even for moderately rocky ground, the method will push small and medium rocks out of the way.

In article <1017481119.920283@aknx2.orcon.net.nz>,
usenetreplies@hotmail.com says...
Seems like some selectivity before the preamp is in order. What is the
spacing in frequency of your 100 watt station and your 50 KW station? I
would guess any preamp will be overloaded by the 50 KW station unless
some selectivity is put in front of it like a pass/notch cavity, helical
type resonators, a tuned stub to notch the 50 KW transmitter. Heck, if
you get the front end cleaned up, you may not need a preamp and without
the RX being de-sensed, you may be ok. This may also lead to an answer
why the RX antenna polarity seems wierd. But this is just my opinion...

Unfortunately, that doesn't work very well. The loop Q is too high,
so a 5% excursion is so far down the curve that induced parasitic
currents tend toward nil. But if you *drive* both loops, you can get
directional patterns. (Feeding the monster can be a bitch, though.)

> wavelength long regardless of the length (wavelength) of the vertical
> element (1/4 or 1/2 or 5/8 wavelengths)?

Not for optimum performance. A 1/2 wave needs no radials. 1/4 wave
radials under a 5/8 antenna are not very good. Sure, they work, but
not near as well as they should. A 5/8 antenna wants to really see
another 5/8 antenna below it, to realize the gain it's capable of. But
then it becomes a dual 5/8 collinear instead of a 5/8 ground plane. If
I couldn't use a lower 5/8 section, or a set of 5/8 radials as the
lower section of a collinear, I'd use a set of 3/4 wave resonant
radials. The pattern will be better than with 1/4 wave radials. Check
out
http://web.wt.net/~nm5k/acompari.htm. Shows some of the patterns you
will have using different types of ground planes and radial lengths.

It is a disc yagi with a coffee can feed. The critical dimensions for disc yagis are the disc diameters and spacings, same as any yagi. A length of all thread rod makes a convenient boom, fender washers make the elements. Use jam nuts to hold everything together. You can trim the washers down with a file, with the washer spinning in a lathe (or drill press) held by a mandrel. Disc diameters are approximately the same as for normal yagi element lengths, after accounting for boom effects.

Looks like a pringles can antenna type thing that's floating around for WLAN stuff on 2.4Ghz. They've also adapted this to a "shotgun directional" type antenna as well.

http://www.seattlewireless.net/index.cgi/BuildingYagiAntennas

Somthing like that, perhaps?

Sorry Jack, you didn't start an argument. It's just amateurs being amateurs and professing their own personal viewpoint. Each is just as valid as the other. It's just that some hams think that their world view is correct and those of us that use the B&W aren't. They are wrong, we are all correct just look at the problem differently.
Dave WD9BDZ

BTW: This posting should bring down the wrath of the purists upon me but so what. I do my thing and they can do theirs.

Source record: 145822

Washing a ground rod in the ground is not a good thing to do
especially if you are going to use it
as a lightning ground. Washing it in loosens the soil around the rod
(pipe) and the earth never
will pack in close again. You will have a loose ground rod with poor
conductivity. Even digging
a hole with a post hole digger and refilling it again is not a good
way to go. Again the earth is not
closely packed as undisturbed earth. They need to be driven into
undisturbed earth for best
performance.

The connections would be better made using a welding process rather
than soldering the joints.
Solder will melt with a lightning strike and you will loose the
connection. Clamping is better than
soldering.

Well, I know for the real FM hounds, there are beams available that are huge;
that have booms more than 30 feet long.

I've also noticed that there are some real high-end FM tuners available, for
prices ranging up to $5000 or $10,000.

Still, even with this stuff, I don't think you're going to have much luck,
trying to pick up a 100 watt station several miles away with a 50K devil in the
neighborhood.

It would be cheaper to move :-)

One must first come to grips with the simple fact that there's no such thing as an all-band antenna. (It is simple and certain that you can force feed an antenna to radiate on bands it was not intended to work. It is just as simple and certain that such an "all-band" antenna will neither deliver optimum performance nor deliver predictable, repeatable radiation patterns. Radiate? Yes. Perform? No.)

Take a look at the 130 ft all-HF-band dipole on my web page and tell
me where I went wrong. I work all 8 HF bands without an antenna tuner.
Why would the radiation patterns not repeat? Besides the relatively
low losses in the ladder-line, where is the power going that would
make it not perform?

In particular, check out the almost 11dBi gain in the four lobes
on 10m with TOAs of 12 degrees. The losses in the ladder-line are
about 0.5dB. The matched line loss in LM-400 would be about 0.6dB.
Where did I go wrong?

Yes, but you have absolutely no control over the network Q. If the Q needs to be 1000 and your inductor unloaded Q is 20, you're in deep doodoo. And if you really do have "pure" reactances, you're still in deep doodoo because the matched BW is negligible.

I doubt anyone here really cares what type of antenna anyone uses
here. I know I sure don't. If you want to use intentional resistance
to get an easier match, be my guest. As far as being correct or not, I
don't even know what the "problem" is, so I don't see how I could have
much to comment on it. As far as the functioning of the B/W antenna, I
don't think I was incorrect. Someone would have jumped on me by now if
I were. Or at least I would hope so anyway. MK

I might also mention that the copper pipe method does not meet NEC code. In the event of a strike, your insurance COULD use that fact against settling your claim. The contradiction is that NEC usually requires a single ground rod, and if the ground resistance measures above 25 ohms, requires one additional rod. The problem is that no further resistance measure is required!

5895. Optimum SWR for multiband magloops?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-31 13:07:51 UTC
From: Frank van Wensveen <frankvw@euronet.nl>
Message-ID: <362eau4gl3132p9qm8qq06329ffboml2jd@4ax.com>
Source record: 145833

Hi everyone.

I'm currently working on a magnetic loop antenna. Since MFJ manages to cover 40-15m with a 36" loop, I decided I would do the same. :-) (Yes, I know, it's a compromise, but for me the advantages outweigh the sacrifice in efficiency.)
Tuning the loop is no problem. Except that the SWR goes up on the higher bands. At 40 and 20 it's 1.1:1 and 1.3:1 respectively, but on 15 it's 3:1.

What's the best possible SWR on all bands? (And what's the SWR on all bands on that MFJ Wundermachinen?)
And, more important, what is going on here? What makes the SWR go up so sharply as frequency increases?

I've tried several coupling loops, both from massive copper wire (electrical installation wire) and coax faraday loops (the kind with the shields soldered together at the bottom (feeding) point and center to shield at the top point). However nobody has managed to explain to me yet what exactly goes on in the coupling loop.

All response is appreciated!

73,

Frank PA3GMP

The Q of a *doubly* loaded L network, using two
lossless and opposite reactances, is

Q = 0.5*sqrt(Rp/Rs - 1)

So it depends only on the resistance ratio. If
load and generator reactances exist they can
usually be absorbed into the L network reactances.
The Q *at resonance* then depends on the remaining
modified values of the resistances Rp' and RL'.
Note that if Rp nearly equal to Rs the selectivity
is almost zero.

Quoting the ARRL Antenna Book: "This simple feed (small loop
gamma match) will provide better than 1.7:1 SWR over a 2:1
frequency range." Thus, outside of the 2:1 frequency range,
we can infer that the SWR will be greater than 1.7:1.

You can hydraulically sink a rod, but you have to do it the right way.
If you try to wash a hole in, the rod will be loose, because the dirt
you've washed out of the hole is lost. But there is a better way.

Dig a mud hole about the size of a quart mason jar. Fill it with water.
Now ram the ground rod into the hole and start to churn it up and
down like you were churning butter. It will start to sink rapidly because
dirt will be forced hydraulically up the hole the rod is forming and will
be retained in the larger mud hole at the top.

Add water as necessary to keep the mud hole filled as you progress.
When you reach the desired depth, walk away. Don't come back until
all of the water is gone from the mud hole. Then fill the mud hole back
up with the dirt you shoveled out to make it.

The result of this activity is a solidly installed ground rod, because
the mud will settle back down around the rod in the hole as it dries,
sealing it in for a good tight fit to the surrounding undisturbed soil.

This technique works very well and very rapidly in good soil. In rocky
soil, you may have to pound on the rod occasionally as you progress
in order to break any rocks you hit.

>Even digging
>a hole with a post hole digger and refilling it again is not a good
>way to go. Again the earth is not
>closely packed as undisturbed earth. They need to be driven into
>undisturbed earth for best
>performance.

The earth will resettle in a couple of years (except in very dry climates).
If you do measurements, you'll notice the ground connection improving
over time. In very dry climates, it may take many years for the earth to
resettle, so this isn't a good installation method in that sort of climate.
But in very rocky soils, you may have no other realistic choice but to
use this method.

>The connections would be better made using a welding process rather
>than soldering the joints.

>Solder will melt with a lightning strike and you will loose the
>connection. Clamping is better than
>soldering.

The National Electrical Code *forbids* soldered ground connections.
Use an approved clamp for the reason given above, or *cadweld* the
wire to the rod using an approved cadweld kit.

You may be tempted to both solder and clamp. Don't do it. There's
no way to realistically test the integrity of the connection if you do.
The solder will make the connection *appear* to be low resistance
even if the connection is poor and unable to handle heavy currents.
With just the clamp, you can measure the quality of the connection
with much greater confidence. (Do monitor your earth connections
from time to time as a part of routine preventative maintenance.)

Outlook Express or Explorer.

(There are some "features" you can't turn off in OE and Explorer
that leave you vulnerable to attack. So the best course is to
completely avoid the use of these two programs. A couple of
alternatives are Eudora for email and Opera for browsing.)

I strongly recommend that you switch to a plain ASCII text
newsreader (and email client too) to avoid this sort of attack
in the future. A very good one for Windows users is Forte's
Agent, available at www.forteinc.com . It is immune to the
usual sorts of attacks because it can't execute any
embedded malicious code sent to it.

Of course, don't *ever* click on any unsolicited attachments,
"cards", or the like sent to you as part of a message or email.
That's just dumb, and leaves you wide open to all sorts of
malicious attacks. Delete without opening everything other
than plain ASCII text. (Note, Word documents and HTML
coded messages are inherently risky, don't send them, and
don't open any sent to you.)

Four lobes; that would leave four big gaps in coverage, eh?
How do you fill those in? Rotate the 130' dipole?

Hi Gary,

THIS is EXACTLY the advice MS offers for solving their security
problem with both OE and IE. The net effect is that it makes IE
utterly useless for those "features" some page designers tout here as
being in demand (the stale argument of numbers proving that IE is the
clear market winner). THIS is EXACTLY the advice ignored by those who
embrace the MS as technology leader myth.

>While it is likely that your current problem is a hoax, real trojan horse
>programs can be sent to you via the Javascript mechanisms in
>Outlook Express or Explorer.

Javascript is an abomination that headed south once MS started adding
"enhancements" and "corrections" to the concept. Unfortunately NS
followed suit to force a compatibility war that they've lost to the
sucker punch of user inertia (the users having once found a browser
installed - guess who's - they turned off their minds to all issues).

This debacle is not to be confused with those programs called Java
Applets (frequent) and Java Applications (rare). Each of these "could
be" as malicious, but that would be only through your explicit choice
from a variety of many more benign alternatives. If you do nothing to
change the Java environment on your machine (and Java is not going to
do it behind your back); then there is no way a Java Applet can harm
your machine or data (or reveal it to others). Java is a secure
programming language with a very fine-grain control over what can and
cannot be done on your system.

5906. ICOM AT-150 Antenna Tuner and IC-751 Cable?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-31 18:22:32 UTC
From: Mike Jordan <mjordan@europa.com>
Message-ID: <3CA753E8.3050108@europa.com>
Source record: 145844

I have a AT-150 auto antenna tuner on my Icom 745. It uses the
OPC-137 cable to connect the two. Can the same cable be used to
connect the AT-150 to an ICOM 751? If a different cable is needed,
what is the number that I need to ask for at HRO or AES?

Thanks

Mike

5909. Re: Optimum SWR for multiband magloops?

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-31 20:03:53 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <a87q38$g3l$1@paris.btinternet.com>
Source record: 145848

There must be at least TWO variable components in ANY device which matches an antenna to a feedline. An antenna tuner always has at least two knobs on the front.

But the usual magloop has only one variable control the - main tuning capacitor. The second control is fixed and set for one band only. The second control is the FIXED DIAMETER of the small coupling loop to the coax feedline. It is a critical Z-matching component. In effect, it adjusts the fractional turns ratio of a transformer formed by the main and small loop.

So when changing bands, if only the tuning capacitor is adjusted and the coupling loop diameter remains fixed, then a shift in SWR away from 1:1 is sure to occur.

So adjust the diameter of the coupling loop for 1:1 SWR on your favorite band and hope for the best on the others.

Program MAGLOOP4 will tell you (and a lot of other things) how much the diameter of the coupling loop must be changed to obtain a 1:1 match when changing from one band to another. Just model a loop, do nothing except change frequency, and observe how small the coupling loop diameter changes.

It will be found the coupling loop also changes with antenna height above ground. This is not surprising since the ground loss resistance induced in the main loop is a function of height above ground.

Download MAGLOOP in a few seconds from website below. Run immediately. Enter basic data. Results in milli-seconds. What-if? operation.

By the way, a coupling loop is much preferable to a gamma-match. And a bare, self-supporting coupling wire, unconnected to the main loop, is preferable to a screened loop constructed from coax. The handbooks need bringing into the 21st century.

Actually George you are the one comparing apples and oranges.
How the heck did we get on to the subject of Log Periodics. But since
you bring them up just another example of a low to no gain
frequency agile antenna design. Beginning to see a pattern here?

> The T2FD is used in field
>applications where portability is the most important consideration.

Portability is just fine but frequency agility is more important.
Unless of course you are portable enough to dodge incoming.

>surplused.

Sorry they usually cut the tower guys and there isn't much left when
it impacts the ground. The aluminum recycle guy is usually the only
one interested.

>There's a big Grainger fixed LPA at the CG receive site in VA
>which always makes me drool when I pass it, and an AS-3195 (rotatable 3-30

>curious about the disposition of.

You might get luck with that one I have watched a number bite the dust, literally, recently.

But back to the subject at hand TFDs are used for frequency agility. My point to the original poster was that, not LPAs. Sure he can cut a efficient dipole for one frequency and stay on it, folks that do that are referred to as targets.

Although 'electronics' folk commonly tin the ends of wire that are then secured in some kind of mechanical fastening (screws etc), it is not a wise practice.

It seems a neat way to stop the strands of the wire from spreading, however one will often find the screws of such a connection apparently loosen. This is usually caused by cold flow of the solder under the pressure of the screw rather than the screw undoing itself.

An old rule was that connections should not depend on the solder for mechanical integrity. This seems to have gone by the wayside in PCB construction for instance, but I suggest that it is a wise approach for any conductors that carry substantial current, and essential for protective conductors like the AC mains protective earth and lightning down conductors.

Lightning down conductors should have test links or other means of isolating individual earth electrodes to periodically measure the performance of components of the system.

It is highly likely that in your area, regulatory codes or standards apply to electrical installations, lightning protection systems, and anything that connects to or between these wiring systems.

The earthing of your tower would be regarded as lightning protection in most places, and may be subject to mandatory requirements.

I have a 33ft rotatable dipole if the 130ft dipole doesn't give
me the coverage I need. I have an A/B knife switch between the
two antennas. As often as not, the 130ft fixed dipole beats
the rotatable dipole in the rotatable dipole's best direction.
Note that I use the ladder-line fed 33ft rotatable dipole on
20m-10m and it is a non-resonant length on all bands except 20m.

My ladder-line length selector gives a good enough match with only one
variable component. If the 450 ohm SWR is between 4.5:1 and 18:1, the
50 ohm SWR at a current maximum point will be less than 2:1.

5915. Re: Installing a good station ground system

Newsgroup: rec.radio.amateur.antenna
Date: 2002-03-31 23:28:58 UTC
From: Reg Edwards <g4fgq.regp@btinternet.com>
Message-ID: <a8863pdmt1@knossos.btinternet.com>
Source record: 145854

A solitary 6-feet rod is next to useless as a RADIO ground unless immersed in salt water.

So although there may be some national (Federal?) 60Hz power distribution regulations which insist on a 6-feet ground rod, by all means connect such a rod to your radio ground but don't solely depend on it for radio purposes.

It may be of interest, a 6-feet ground rod in average sort of soil has a resistance to Mother Earth much greater than 25 ohms. Even a pair of spaced rods may have a resistance considerably higher than the regulation maximum.

To find resistance of a ground rod of given length and diameter in a soil of given resistivity, download program EARTHRES. Resistance of a bunch of 2, 3 or 4 spaced rods can also be found. Also of a set of N radials of given length, diameter and depth.

Download EARTHRES from following website in a few seconds and run immediately. It is not zipped up. The program can be used in reverse to estimate soil resistivity from simple amateur measurements made on various electrodes. (In this advanced age there are commercial hand-held instruments to do such jobs).

It's less inconvenient than setting up a 1 KW radio transmitter with a 500-feet vertical antenna and measuring groundwave field strength at distances of 1, 2, 5, 10, 20 and even 100 miles provided it's in daylight.
